# THE FINAL REPORT OF THE ROYAL COMMISSION ON NATIONAL PASSENGER TRANSPORTATION

## SUMMARY

The Royal Commission on National Passenger Transportation recognizes that transportation touches everyone's life and that information concerning our recommendations for Canada's passenger transportation system in the 21st century must reach as many Canadians as possible.

For these reasons, the Royal Commission is publishing this summary of our final report, *Directions.* The summary provides a brief overview of our principal findings and recommendations; we hope that it will persuade the reader to read the final report.

*Directions: The Final Report of the Royal Commission on National Passenger Transportation* is published in four volumes and is available through local public libraries across the country. It may also be purchased directly from the Canada Communication Group — Publishing and is available through your local bookseller. To find out how you may purchase the complete four-volume set of *Directions,* or the sub-set of Volumes 1 and 2 (Findings and Recommendations, and Supporting Documentation), please call: (819) 956-4802.

## WHAT THE GOVERNMENT OF CANADA ASKED THE ROYAL COMMISSION TO DO

Around the world, transportation is undergoing rapid, major change. Many countries are trying new ways to finance transportation infrastructure and to deliver passenger transportation services to the marketplace. Changing government economic regulation over the delivery of passenger transportation services has resulted in new approaches to meeting travellers' needs.

This pace of change will continue and Canadians cannot ignore these innovations in other parts of the world and the challenges that they present. As the economies of nations become more and more interdependent, the choices that Canadians make about passenger transportation projects and investment will affect Canada's economic success in the global marketplace. It is therefore important to make the right passenger transportation decisions now.

In 1990, Canadians devoted substantially more resources to transportation than to health care (16 percent of gross domestic product (GDP) compared with 9 percent of the GDP). In dollar figures, we estimate that in 1991, Canadians spent between $30 billion to $45 billion, or an average of $1,100 to $1,700 per person, on intercity passenger transportation itself.

Canada has changed dramatically since the MacPherson Royal Commission issued its report on transportation 30 years ago. We believe it is now opportune to develop a new framework for Canada's passenger transportation system, one that will endure well into the 21st century.

The Royal Commission on National Passenger Transportation was established on October 19, 1989, under Part I of the *Inquiries Act*, and given three years ". . . to inquire into and report upon a national integrated intercity passenger transportation system to meet the needs of Canada and Canadians in the 21st century. . . ."

# HOW THE ROYAL COMMISSION WENT ABOUT ITS WORK

Securing a thorough understanding of the passenger transportation system as it is today is a necessary prerequisite to making recommendations for the future. To gain that understanding, the Royal Commission undertook three major initiatives: consultations, international study and research.

## CONSULTING WITH CANADIANS

Through public hearings across the country, written submissions, toll-free telephone lines, meetings and seminars, we listened to interested Canadians. These included travellers and providers of transportation infrastructure and services, as well as governments, taxpayers, unions, regulators and special interest groups such as people with disabilities and seniors. Much of what Canadians told us was reported in *Getting There*, our Interim Report.

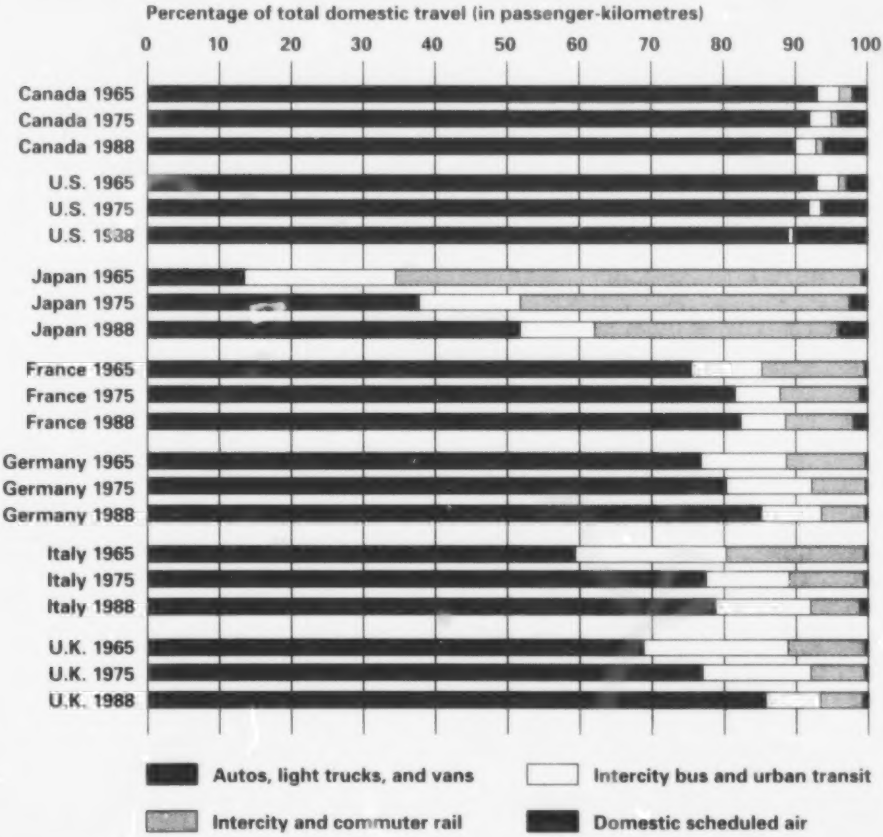
## STUDYING THE PASSENGER TRANSPORTATION SYSTEMS OF OTHER COUNTRIES

We also looked at how other countries are dealing with passenger transportation issues. We discovered that Canada is not alone in questioning the traditional ways of making passenger transportation policy and investment decisions, nor in seeking new ways to resolve transportation issues. Governments around the world are exploring ways to improve the efficiency of their transportation systems.

Canadian travel patterns are broadly similar to those of other developed countries, although there are some differences. The following chart shows that Canadians share a strong attachment to the car with travellers in other developed countries. The train is a more important passenger travel mode in Japan, and a somewhat more significant mode in Western Europe than in Canada or the United States. Most countries, however, are seeing the same long-term decrease in the importance of train and bus travel as has been observed in Canada. Airplane travel, by contrast, has increased its share of passenger travel everywhere. With their much larger land masses, Canada and the United States rely on air travel far more than Japan or Western Europe.

*Chart 1*

INTERNATIONAL COMPARISONS OF MODAL SHARES IN TOTAL DOMESTIC TRAVEL, 1965, 1975 AND 1988



**Sources:** Royal Commission staff calculations based on data from Statistics Canada, the European Conference of Ministers of Transport, and a number of U.S. and Japanese sources. For details consult the Notes to Chapter 2 in Volume 2 of the final report.

**Note:** Total domestic travel includes both urban and intercity travel.

Several countries have undertaken major transportation studies and have already begun implementing changes; others have relaxed government controls and economic regulation over their transportation carriers. Some have studied ways of setting prices that reflect the true costs of transportation services and facilities, while others have experimented with alternative transportation ownership and administrative arrangements.

## RESEARCHING PASSENGER TRANSPORTATION

Among other issues, our Research Program examined:

- travel patterns in Canada;
- the costs and who pays them;
- the effects of transportation on the environment;
- the safety of each mode; and
- accessibility for people with disabilities.

We concluded that the way the passenger transportation system in Canada is managed is no longer adequate. Why?

- most travellers do not pay the full costs of the passenger transportation services that they use, and prices do not reflect a traveller's use of the system;
- in no mode are costs entirely covered by fares, licences and fees;
- individual carriers face different rules and regulations;
- costs are higher than necessary because governments do not always invest in projects that result in the best value;
- environmental and other social costs are rarely factored into the costs of the passenger transportation system; and
- taxpayers lack information about why decisions are made and how their tax dollars are spent.

# OUR APPROACH

## OUR GUIDING PHILOSOPHY

While a passenger transportation system heavily subsidized by the taxpayer may have been appropriate for Canada for the past 125 years, it is not the right one for Canada in the 21st century. Now, and in the decades ahead, Canada needs a system supported by the travellers who use it and not by government subsidies, departments and central controls. Passenger transportation should be treated more like a business.

Instead of governments controlling who may carry passengers, we believe in a system controlled by consumers in the marketplace. Rather than governments providing most of the infrastructure, we believe the marketplace should do that job, with governments confining themselves to the roles of referee and policy maker. As a change from centralized and often remote jurisdictional arrangements, we believe transportation-related responsibilities should be moved to the level of government closest to the people that can most efficiently handle the responsibilities.

In the past, passenger transportation has depended on major funding from general taxpayers, many of whom travel only a little or not at all. We believe that the system should now be self-sustaining; travellers should get what they pay for and pay for what they get.

## OUR METHOD: A FRAMEWORK

The Royal Commission took a comprehensive approach to the passenger transportation system. We wanted to help resolve not only today's issues and problems, but those of tomorrow as well.

To accomplish this, we adopted a long-term passenger transportation framework. What do we mean by "framework"? We mean the laws, regulations and institutions that govern transportation.

Too often today, passenger transportation decisions are inconsistent, short-term and wasteful; with a guiding framework in place, future passenger transportation decisions will be coherent, consistent and less expensive after all costs paid by all parties are taken into account.

## OUR DIRECTIONS: GOAL AND OBJECTIVES OF THE TRANSPORTATION SYSTEM

As the foundation for the framework, the Royal Commission set a goal for passenger transportation and developed four objectives that we found Canadians generally support, and that we believe should guide Canada in the future. We propose Canadian solutions to Canadian problems.

We believe that the main goal of Canada's intercity passenger transportation system should be to move people to where they want to go. Travellers should be able to choose the transportation services they want, get what they pay for, and pay for what they get. They should not be encouraged to go places or travel by particular modes due to government policies or subsidies that favour particular destinations or modes.

We recommend that the passenger transportation system be guided by the following policy objectives:

(a) safety;

(b) protection of the environment;

(c) fairness to taxpayers, travellers and carriers; and

(d) efficiency, so that services are provided only where benefits to the individual traveller equal or exceed the cost, and given levels of service are provided at the lowest possible cost.
**Recommendation 4.1**

What about other possible objectives for the passenger transportation system, such as nation-building or regional development? During the Royal Commission's public hearings, some Canadians spoke about the importance of passenger transportation in nation-building and regional development. Nation-building and regional development should be objectives of the various levels of government; but should they be identified as passenger transportation objectives? We believe that the answer is no. Passenger transportation policies should not be guided by objectives of nation-building and regional development for the following reasons.

*Nation-building:* In general, the passenger transportation system is mature, and most Canadians are well served by a number of modes. We do not believe that any single transportation project, route, network or mode is likely to stand out today, as the transcontinental railway once did, as a symbol that unites Canada. We doubt that any new passenger transportation mega-project would contribute to building the nation — beyond its contribution to the nation's economy, which can be assessed using the criteria we suggest.

*Regional development:* We recognize that passenger transportation infrastructure and services can play a vital role in the development and functioning of national and regional economies. From our research and consultations, however, we concluded that separate and additional regional development benefits are unlikely to be substantial and these benefits alone should not be used to guide passenger transportation policies.

We therefore recommend that:

- Governments pursue nation-building and regional development objectives through other programs, rather than using the passenger transportation system.
  **Recommendation 4.2**

## HOW WILL OUR RECOMMENDATIONS AFFECT TRAVELLERS?

**Travellers should pay for the true costs of the travel services they use, including those for damages to the environment, and people who do not travel should not have to pay for those who do.**

Taxpayers will no longer subsidize travellers as they do under the present system.

We recommend that:

- Each traveller pay the full cost of his or her travel, and travellers, in total, pay the full cost of the passenger transportation system, including those costs related to protecting the environment, safety and accidents.
  Recommendation 4.3

Some Canadian travellers may be unhappy about our recommendations that they be charged prices and taxes at a level that covers the cost of their transportation. It should be remembered that all the costs of passenger transportation today are paid either through fares, or through taxes and income taxes. We are simply proposing that the system would be fairer to all if the burden of payment shifted from those who do not use the passenger transportation system to those who do.

**At present, taxpayers knowingly support the transportation system through direct subsidies and unknowingly, through hidden subsidies.**

Direct subsidies are those that governments show in their budgets as amounts transferred to carriers or travellers from the taxpayers. Hidden subsidies are those that are less visible to the public since they are not identified in government accounts.

Under our approach, travellers and carriers would pay the full costs of the passenger transportation system, but these costs would be based on principles of efficient investment and pricing. Travellers would not be paying for a passenger transportation system that is wasteful because it has too much or too little capacity, or capacity of the wrong type and in the wrong place. Travellers and carriers would be able to purchase services at the lowest possible prices for the greatest benefit.

Table 1 illustrates the various components of the intercity passenger transportation system.

*Table 1*
COMPONENTS OF THE TRANSPORTATION SYSTEM

| Mode | Carrier | Infrastructure | | |
|---|---|---|---|---|
| | | **Terminals** | **Links** | **Traffic control** |
| **Road** | Cars | Car parking | Roads (including bridges) | Police, road signs and signals, traffic control laws and regulations |
| | Buses | Bus terminals | | |
| **Air** | Airplanes | Airports (including runways) | Air navigation systems | Air traffic control |
| **Rail** | Trains | Stations | Railway tracks | Dispatch, signal systems |
| **Water** | Ferries | Ferry terminals (including wharves and ferry slips) | Waterways and canals (including navigational aids) | Vessel traffic services |

Tables 2(a) and 2(b) illustrate the comprehensive system-wide costs of intercity domestic travel and who pays these costs today. Under "users," the tables show estimates of costs paid by travellers and costs paid by carriers that will be passed on to travellers.

Under "others," the tables show costs that are not borne by travellers. For the most part, these are costs borne by general taxpayers, and also include estimates of environmental damage that is now borne by the public. Costs borne by others represent an overall measure of subsidies to travellers.

Table 2(a)

### ILLUSTRATIVE SYSTEM-WIDE ANNUAL COSTS OF INTERCITY DOMESTIC TRAVEL, PAID BY USERS AND OTHERS, 1991, IN 1991 DOLLARS

| Average costs: cents per passenger-kilometre | | | | | | |
|---|---|---|---|---|---|---|
| | Car | | | Bus | | |
| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 0.0 | 2.1 | 2.1 | 0.0 | 0.3 | 0.3 |

| **Accident** | 0.1 | 0.0 | 0.1 | 0.2 | 0.0 | 0.2 |
| **Special trans. tax/fee** | 0.6 | –0.6 | 0.0 | 0.4 | –0.4 | 0.0 |
| **Vehicle/Carrier** | 14.4 | 0.1 | 14.4 | 7.4 | 32.8 | 40.2 |
| **Total** | **17.3** | **3.8** | **21.1** | **10.9** | **33.0** | **43.9** |
| | Ferry | | | All intercity travel | | |
| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 0.0 | 4.7 | 4.7 | **0.2** | **2.2** | **2.4** |
| **Environmental** | 0.0 | 2.0 | 2.0 | **0.0** | **0.6** | **0.6** |
| **Accident** | 0.1 | 0.0 | 0.1 | **3.3** | **0.2** | **3.4** |
| **Special trans. tax/fee** | 0.9 | –0.9 | 0.0 | **1.1** | **–1.1** | **0.0** |
| **Vehicle/Carrier** | 24.1 | 11.6 | 35.7 | **11.2** | **0.2** | **11.4** |
| **Total** | **25.1** | **17.4** | **42.5** | **15.8** | **2.0** | **17.8** |

*Table 2(b)*

## Illustrative System-Wide Annual Costs of Intercity Domestic Travel, Paid by Users and Others, 1991, in 1991 Dollars

| Totals: $ millions | | | | | | |
|---|---|---|---|---|---|---|
| | Car (210 billion pass-km) | | | Bus (3.3 billion pass-km) | | |
| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 0 | 4,486 | 4,486 | 0 | 10 | 10 |
| **Environmental** | 0 | 1,211 | 1,211 | 0 | 8 | 8 |
| **Accident** | 7,874 | 172 | 8,046 | 13 | 0 | 13 |
| **Special trans. tax/fee** | 2,461 | −2,461 | 0 | 9 | −9 | 0 |
| **Vehicle/Carrier** | 22,817 | 0 | 22,817 | 277 | 8 | 285 |
| **Total** | **33,152** | **3,408** | **36,560** | **299** | **17** | **316** |
| | Airplane (25 billion pass-km) | | | Train (1.4 billion pass-km) | | |
| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 556 | 845 | 1,401 | 41 | 0 | 41 |
| **Environmental** | 0 | 247 | 247 | 0 | 9 | 9 |
| **Accident** | 25 | 0 | 25 | 3 | 0 | 3 |
| **Special trans. tax/fee** | 149 | −149 | 0 | 6 | −6 | 0 |
| **Vehicle/Carrier** | 3,595 | 0 | 3,595 | 104 | 459 | 563 |
| **Total** | **4,325** | **943** | **5,268** | **154** | **462** | **616** |
| | Ferry (0.85 billion pass-km) | | | All intercity travel (240 billion pass-km) | | |
| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 0 | 40 | 40 | **597** | **5,381** | **5,978** |
| **Environmental** | 0 | 17 | 17 | **0** | **1,492** | **1,492** |
| **Accident** | 1 | 0 | 1 | **7,916** | **172** | **8,088** |
| **Special trans. tax/fee** | 7 | −7 | 0 | **2,632** | **−2,632** | **0** |
| **Vehicle/Carrier** | 205 | 98 | 303 | **26,998** | **565** | **27,563** |
| **Total** | **213** | **148** | **361** | **38,143** | **4,978** | **43,121** |

**Note:** **In order to illustrate smaller components, averages are shown to the nearest tenth of a cent and totals to the nearest million dollars. In general, cost estimates are approximate and are not accurate to this level of precision.**

The tables show that bus travel is the least costly mode, with an average total cost of 9.5¢ per passenger-kilometre. We estimate that bus travellers pay all but 0.4¢ per passenger-kilometre of this. Car and airplane travellers receive a somewhat larger subsidy; the general taxpayer and the public subsidize car travel by an estimated 1.8¢ per passenger-kilometre and air travel by 3.6¢ per passenger-kilometre. These subsidies cover infrastructure, environmental and accident costs not paid by users, plus small direct subsidies paid for air travel in some provinces, and are net of special taxes collected by federal or provincial governments.

The largest gap between "users" and "total" costs are for train travel (33.0¢ per passenger-kilometre) and ferry travel (17.4¢ per passenger-kilometre). This is due to large, direct subsidies from the taxpayers to travellers using passenger rail and some ferry services. For the interpretation of these tables, see *Directions*, Volume 1, Chapter 3.

Our recommendation that travellers pay the full costs of their travel means that travellers using a public mode of transportation such as the bus, train, commercial airplane or ferry, as well as those travelling by private car or private airplane, will pay fares, taxes or fees sufficient to cover their share of the full cost of providing services they use. The recommendation also means that the burden on the general taxpayer would be reduced accordingly.

In paying the full costs, travellers should also pay, through either a portion of their fare, a tax or a charge, for any environmental damage they cause and for all safety and accident costs associated with their travel.

Environmental damage charges are addressed in **Recommendation 7.4** and **Recommendation 7.5** and include, among other things, the costs of clean-up and mitigation, and the administration of environmental policies and regulations. **Recommendation 7.6** stipulates that the charges be applied equally to all modes.

For more information on the environment, and the complete text of Recommendations 7.1 to 7.7, see *Directions*, Volume 1, Chapter 7.

Charges for safety and accident costs will include the cost of safety services provided by governments, and health care costs currently borne by the health insurance system.
**Recommendation 8.1**

For more on safety and the complete text of Recommendations 8.1 and 8.2, see *Directions*, Volume 1, Chapter 8.

## ACCESS FOR PEOPLE WITH DISABILITIES

Nearly 10 percent of Canada's adult population has a transportation-related disability. The following table provides an estimate of the number of Canadians with transportation-relevant disabilities by type of disability.

*Table 3*
*NUMBER OF PERSONS WITH TRANSPORTATION-RELEVANT DISABILITIES, BY TYPE OF DISABILITY, 1990*

| | Number | Percent[a] |
|---|---|---|
| **All Canadians aged 15 and over with transportation-relevant disabilities** | 1,879,615 | 100.0 |
| Mental disability | 714,398 | 38.0 |
| Hearing impairment | 648,780 | 34.5 |
| Sight impairment | 417,990 | 22.2 |
| Speech impairment | 159,843 | 8.5 |
| Wheelchair or walker use | 132,660 | 7.1 |
| Blindness | 42,176 | 2.2 |
| Disability unspecified | 37,052 | 2.0 |

**Sources: Hickling Corporation, using data from Statistics Canada's Health and Activity Limitation Survey, 1987, with projections to 1990; *Transportation for People with Disabilities: A Policy Review and Analysis*, a report prepared for the Royal Commission on National Passenger Transportation, RR-01, March 1991, p. 5.**

**a. Figures will add to more than 100 percent because some people have multiple disabilities. Figures include people living in institutions but exclude those confined to the home (an estimated 37,600).**

## People with disabilities should have wider access to the passenger transportation system

While the Royal Commission acknowledges that governments and industry have taken important steps to provide access to intercity passenger transportation services for people with disabilities, our approach goes further. We recommend that:

- Travellers with physical or mental disabilities have opportunities similar to those enjoyed by all Canadians to use public passenger transportation.
  **Recommendation 4.4**

We further recommend that:

- Governments establish a goal that all travellers in Canada have access to public transportation in a safe, reasonably comfortable and dignified fashion, irrespective of physical or mental ability.
  **Recommendation 9.1**

For carriers and providers of infrastructure, we recommend: that they begin immediately to ensure that their specifications for new equipment and infrastructure provide continuing improvements in accessibility; that carriers cover an attendant's fare if they decide that, for safety reasons, an attendant is needed during a trip; and that they ensure that any personnel who might be required to assist travellers with disabilities are trained to deal with such travellers with sensitivity and understanding.
**Recommendations 9.3, 9.8 and 9.9**

We also recommend an expanded role for the National Transportation Agency (NTA) regarding people with disabilities, more specifically: that the NTA establish minimum standards of passenger accessibility; that it take more active responsibility for ensuring that transportation

services become more accessible to people with disabilities; and that the NTA be appointed the referee to mediate disputes regarding the need for an attendant.
**Recommendations 9.2, 9.4 and 9.7**

We further recommend that:

- Through consultation among groups representing people with disabilities, carrier associations and the National Transportation Agency, a mechanism such as a coded identification card system be devised that would indicate quickly to carrier personnel the kinds of services needed by each traveller with a disability, including whether or not the traveller requires an attendant for safety or other reasons.
  **Recommendation 9.6**

For more information on access to transportation for people with disabilities and the complete text of Recommendations 9.1 to 9.11, see *Directions*, Volume 1, Chapter 9.

## HOW WILL OUR RECOMMENDATIONS AFFECT CARRIERS?

**Passenger transportation carriers should face market pressures to respond to consumer preferences and to reduce costs, to improve efficiency, and to pass resulting savings on to travellers.**

### Canadian passenger transportation and the marketplace

We recommend that:

- Competition and market forces be the prime agents in providing viable and efficient carrier services.
  **Recommendation 4.5**

To achieve this marketplace discipline, governments will make it easier for new competitors to enter the market by eliminating or easing restrictions. All competitors that meet "fit, willing and able" criteria will have the opportunity to supply passenger carrier services. Moreover, these potential new entrants will have equal access to transportation infrastructure so long as they are prepared to pay their share of the costs. And, as we said before, these costs include those imposed by travellers through environmental damage, safety costs and accidents. At the same time, anyone providing passenger transportation services will be able to withdraw these services without undue delay, subject only to adequate notice.

We therefore recommend that:

- Federal, provincial and territorial governments amend their legislation concerning the regulation of intercity buses to reduce entry restrictions to "fit, willing and able" criteria, and require only public notice of route abandonments and publication of schedules and fares.
  **Recommendation 13.1**

- The federal government invite Canadian air carriers to make public proposals for future international air route designations, with the air carrier offering the best package to be granted the route and the reasons made public, and Canadian air carriers be allowed to sell designated international routes to one another.
  **Recommendations 11.3 and 11.4**

- Governments abstain from making any financial contribution that is intended to ensure the survival of air carriers.
  **Recommendation 11.5**

- The federal government amend legislation to make rail track access available to all qualified passenger carriers who are willing to pay for what they use and ensure that all such carriers have a right of access to essential infrastructure and are treated equally in the movement of traffic.
  **Recommendation 6.7**

- Airport and municipal authorities cooperate to ensure unrestricted access to airports by all ground connectors who pay their share of the costs, and the federal government similarly grant all ground connectors open access to federally owned airports and rail stations.
  **Recommendation 15.1**

- The federal government require that all agreements for the sale or lease of federally owned transportation infrastructure include provisions that oblige the operating authority to grant open access to all intermodal connectors on equal terms and conditions.
  **Recommendation 15.2**

**An exception to the rule . . .**

Under current international arrangements, if a Canadian airline is no longer owned and controlled by Canadians, its classification as a "national airline" is jeopardized; this, in turn, may put the airline's entitlement to fly international routes at risk.

Although the Royal Commission recommends no restrictions on ownership of the other modes, we make an exception for air carriers because of this current international regulatory regime.

Regarding ownership of airlines, we recommend that:

- The federal government and the government of Alberta amend their legislation to eliminate the 10 percent ceiling on individual holdings that currently applies to Air Canada and Pacific Western Airlines (the parent of Canadian Airlines International).
  **Recommendation 11.2**

- The federal government retain the existing limits on foreign ownership and control of air carriers.
  **Recommendation 11.1**

- If faced with a potential reduction to only one major Canadian carrier in the domestic market, the federal government use its powers to override limitations on foreign ownership and control for the explicit purpose of, and to the extent required to, ensure competition in the domestic market.
  **Recommendation 11.6**

For more on "ownership" in the air mode, see *Directions*, Volume 1, Chapter 11.

## HOW WILL OUR RECOMMENDATIONS AFFECT PROVIDERS OF INFRASTRUCTURE?

**Suppliers of transportation infrastructure should charge for their services. Those who do not benefit from these services should not have to pay for them.**

Carriers and travellers told us that if they are going to be asked to pay the full cost for terminals such as airports, links such as roads and railway tracks, as well as traffic control services, they want to be sure that what is provided is only what is needed, no more, no less. The Royal Commission agrees and recommends that:

- Terminals, links and traffic control services be priced on a terminal-by-terminal, link-by-link and service-by-service basis.
  **Recommendation 4.6**

- Where there is sufficient competition, or where users are in a strong bargaining position with providers of terminals, links or traffic control services — and so long as there are appropriate charges for environmental damage, safety and accidents — competition and market forces determine prices and investment decisions for passenger transportation infrastructure.
  **Recommendation 4.7**

- Where regulations are required, they be designed to ensure that pricing and investment decisions will be similar to what would otherwise occur through competitive market forces.
**Recommendation 4.8**

## SETTING PRICES

**Travellers should only pay for what they use.**

Prices will reflect the travellers' or carriers' use of each terminal, link or traffic control service and will be designed to encourage neither overuse nor underuse.

And, where the prices do not recover the full cost of providing the service, they will be adjusted to provide for full cost recovery in such a way as to minimize the loss of efficiency.

We therefore recommend that:

- Conventional tolling systems be considered when new or expanded, limited-access highways are required, with tolls set to cover any costs of the road link in question exceeding those recovered by fuel taxes.
**Recommendation 5.6**
- Provincial and territorial governments institute weight-distance taxes for trucks as part of an overall road-financing program.
**Recommendation 5.5**
- Airport operators obtain their funding from site-specific charges on an airport-by-airport basis, rather than through an allocation from the Air Transportation Tax. Charges to travellers will reflect the commercial potential of the airport, not historical costs.
**Recommendations 5.1 and 5.3**
- The operator of the air navigation system obtain funding for that system by charging aircraft operators directly for their share of air navigation and air traffic control costs by using charges that differ

by type of flight, class of aircraft and value of benefits received, rather than an allocation from the Air Transportation Tax. This system would replace the Air Transportation Tax.
**Recommendation 5.7**

A decision to move to a link-by-link charge for the existing road system will be based, in part, on technological feasibility, administrative cost and public acceptability.

For road projects, we therefore recommend that:

- Provincial and territorial governments meet the costs of their highway system, and any agreed upon National Highway System projects within their borders, through fuel taxes and other charges.
**Recommendation 6.6**

For more on investment and pricing and the complete text of Recommendations 5.1 to 5.7, see *Directions*, Volume 1, chapters 5 and 6.

## INVESTING IN TRANSPORTATION

**Regardless of mode, investments will be made only in those passenger transportation projects in which benefits to travellers exceed costs, and in those that yield the highest level of benefits over costs.**

We therefore recommend that:

- For transferring airports to Local Airport Authorities, the federal government's valuation of existing airport capital facilities reflect the commercial potential of the facilities, not historical costs.
**Recommendation 5.3**
- Governments or local airport authorities make airport investments on an airport-by-airport basis and only make new airport investments where costs, including a return on investment, can be expected to be repaid through future revenues.
**Recommendations 5.1 and 5.3**

- In determining the extent of restoration and upgrading required for the national highway network, provincial and territorial governments be guided by a comparison of benefits and costs on individual projects, rather than by uniform engineering standards.
  **Recommendation 6.4**
- Governments invest in high-speed rail infrastructure only if the benefits to the passenger transportation system exceed the costs, and if taxpayers do not have to pay any operating subsidies.
  **Recommendation 12.6**
- Any railway company be allowed to abandon any amount of track without a limit.
  **Recommendation 6.8**
- All responsible agencies, in evaluating safety improvements in different modes, use comparable values for injury and loss of life.
  **Recommendation 8.2**

## HOW WILL OUR RECOMMENDATIONS AFFECT GOVERNMENT?

**Transportation should be moved out of the government tax-and-spend regime into one that is supported and maintained by the users of the system.**

We have said that competition and market forces should be the prime agents in developing a viable and efficient passenger transportation system. There are some functions in the passenger transportation system, however, that can and should only be performed by governments.

- Governments will be responsible for establishing policies in relation to the passenger transportation framework, setting and enforcing standards, gathering and reporting information to the public, ensuring a sufficient level of research, maintaining competition and regulating monopolies.
  **Recommendation 4.9**

Federal, provincial and territorial transportation departments should move toward being small policy-oriented departments. The departments should shed most or all of their operating responsibilities. Government agencies might still be used to provide some carrier services and operate some infrastructure. They will, however, be expected to function without subsidies, and private sector firms will, in general, be free to enter the market in competition with such government operators.

Therefore, we recommend that:

- The federal government transfer all remaining airports to Local Airport Authorities and/or to other types of local operators, and convert the air navigation system from a departmental organization to either a Crown corporation or an independent institution.
  **Recommendations 6.1 and 6.2**
- Each provincial and territorial government establish a Crown corporation, supplemented by an advisory group, to be responsible for providing roads more efficiently and making pricing and investment decisions more transparent.
  **Recommendation 6.3**
- Railway companies offer abandoned rail rights-of-way, under a formal procedure, to governments and then to other railway companies before such rights-of-way can be converted to other uses. All levels of government develop policies, based on explicit criteria, for deciding which corridors they wish to retain for future transportation use and ensure that land so acquired is maintained intact as a corridor.
  **Recommendation 6.9**

We recommend that the federal government:

- Review the *Competition Act* and related policy and, if required, strengthen the powers needed to prevent anti-competitive practices in the intercity bus industry.
  **Recommendation 13.2**

- Extend its regulations governing the anti-competitive practices of computer reservation systems beyond the air mode to take a multimodal approach.
  **Recommendation 15.3**

- Establish the regulations under which any high-speed rail system will operate, including safety and environmental regulations.
  **Recommendation 12.8**

We recommend that the National Transportation Agency:

- Ensure that abandoned railway corridors are offered to governments or other railway companies at a reasonable price.
  **Recommendation 6.9**

We recommend that provincial and territorial governments:

- Implement more-uniform and adequate minimum accessibility standards for intercity buses for travellers with disabilities, or, if that does not occur, the federal government rescind its delegated responsibility for nationally applied accessibility standards in order to ensure more uniformity.
  **Recommendation 9.10**

We also recommend that all governments:

- Further develop travel and transportation data for public use, and the federal government publish an annual report card on the passenger transportation system.
  **Recommendations 16.2, 16.3 and 16.4**

We recognize that the policies of one level of government regarding a mode for which it is responsible can affect other modes that are the responsibility of another level of government. But, as long as all modes are paying their way, as we recommend, this type of interaction is not inherently a problem.

Therefore, we recommend that:

- Decision-making authority of governments be assigned to the level of government that is both closest to the people and most able to efficiently exercise such authority.
  **Recommendation 4.10**

We also believe that our framework can be implemented using a cooperative approach within existing jurisdictional arrangements.

We therefore recommend that:

- A National Highway System be identified by the Council of Ministers Responsible for Transportation and Highway Safety and be operated and maintained through cooperative action of provincial and territorial governments and/or their road agencies.
  **Recommendation 6.5**
- Local or regional governments take policy responsibility for controlling environmental damage when the source and effects are local.
  **Recommendation 7.1**
- The federal government take responsibility when environmental damage from one region affects other regions or countries; continue to strive for development of an effective international strategy to control global warming; and seek to harmonize domestic policies and taxes with the international community.
  **Recommendation 7.2**

## All modes will be treated equally

We recommend that:

- Governments tax and regulate all modes equally.
  **Recommendation 4.11**

- All fuel taxes be used for transportation purposes or as a means of charging for costs, such as environmental damage and health care system costs, caused by transportation.
  **Recommendation 5.4**

- Governments apply environmental emission charges equally to all modes and to non-transportation sources, on as close to a per-unit-of-emission basis as practical.
  **Recommendation 7.6**

- Governments set regulations for the control of environmentally damaging emissions. These regulations should impose similar obligations in terms of cost per unit of abatement on each mode, and treat non-transportation sources of pollutants similarly to transportation sources.
  **Recommendation 7.3**

- Governments separate revenues from environmental emission charges from other passenger transportation revenues and use such funds to clean up the environmental damage, compensate those affected, or lower general tax rates. They should not use such funds to expand or maintain the passenger transportation system.
  **Recommendation 7.7**

## IMPROVING ACCOUNTABILITY AND TRANSPARENCY

**The costs of the transportation system should be transparent, and governments should be accountable for their decisions.**

Passenger transportation decisions made by governments should be clear, obvious and direct, and all costs should be made public. We therefore recommend that:

- Decision making be transparent so that Canadians can understand why governments or their agencies make the passenger transportation choices they make, and so that those making decisions can be held accountable.
  **Recommendation 4.12**

To achieve this transparency in the decision-making process, we further recommend that:

- If agencies that are established to manage transportation infrastructure are monopoly suppliers, the level of government responsible ensure that advisory bodies of travellers and other interested parties are created to counsel management on investment priorities, charging mechanisms and the prices needed to achieve self-sufficiency.
  **Recommendation 16.1**
- Governments clearly report to the public the amount of, and reason for, any continuing subsidies to carriers.
  **Recommendations 12.5, 14.4 and 16.4**
- The federal government allocate resources, and provincial and territorial governments cooperate with the federal government, to ensure the further improvement and collection of travel and other transportation data, and that the data be made available to the public.
  **Recommendations 16.2 and 16.3**
- The federal government publish an annual report card on the passenger transportation system that will include information on the use of the system, subsidies, extent of cost recovery, and degree to which objectives are being met, as well as information on the reliability and safety of transportation.
  **Recommendation 16.4**

## GIVING THE PASSENGER TRANSPORTATION SYSTEM TIME TO ADJUST

We recognize that our proposed transportation framework will differ substantially from the current system and that governments will have to give travellers, carriers and infrastructure providers time to adjust.

We therefore recommend that:

- In cases where time is required to ease the problems caused by steep price adjustments, or where a carrier, a particular carrier service, a terminal or a link is to be given another chance to survive within the new framework, financial assistance be designed to encourage adjustment.
  **Recommendation 4.13**
- If a carrier, a particular carrier service, a terminal or a link cannot survive despite a reasonable period of time for adjustment, the terminal or link be closed or the service discontinued.
  **Recommendation 4.14**

During the adjustment period, any remaining subsidy from the taxpayer be:

- provided, where possible, to move people in the most efficient way, regardless of mode;
- borne by taxpayers in the jurisdiction that makes the decision, not by other transportation users; and
- provided on a declining basis, for a reasonable adjustment period, and then terminated.
  **Recommendation 4.13**

The Royal Commission recognizes four cases in which governments may have to provide transitional subsidies: airports, passenger rail, intercity bus and ferries. We therefore recommend that:

- Whenever applying our principles to airports, including all Transport Canada airports, would result in steep increases in average charges to travellers, governments provide transitional subsidies to be phased out over 10 years. The initial level of subsidy should be based on the current operating subsidy and be used for capital as well as operating expenditures or, if the airport is closed, for other local transportation purposes.
  **Recommendation 5.2**

- The federal government enact legislation to give VIA Rail a mandate to operate on a commercial basis, with the general subsidy having a sunset provision of 10 years. During this period, VIA Rail will have greater freedom to manage, including investment decisions, route selection, service levels and pricing; will be allowed to compete for other services such as commuter services and transporting mail; and will be required to file and publish detailed annual operating plans and financial reports, including the costs and revenues related to individual routes. At the end of 10 years, all routes, excluding remote services, should be unsubsidized.
  **Recommendations 12.1, 12.2, and 12.3**

- If necessary to avoid steep increases in bus fares on particular routes following the relaxation of economic regulation of the bus industry, governments provide transitional subsidies on a declining basis not to exceed 10 years.
  **Recommendation 13.3**

- If necessary to avoid steep increases in fares, governments provide transitional subsidies not to exceed 10 years on individual ferry routes.
  **Recommendation 14.1**

In some cases, governments might choose to continue subsidies to passenger transportation services that are not commercially viable. Such subsidies are not consistent with our framework and, in general, should not be maintained. If, however, governments continue to provide subsidies despite our recommendations, they should do so in such a way as to ensure that services provided are as efficient as possible. In addition, such subsidies should be provided from general tax revenues and not from charges to travellers.

Where governments judge that a subsidy for passenger transportation to remote communities is justified, we recommend that:

(a) the most efficient mode and carrier be used and, where feasible, a competitive bidding process be implemented;

(b) any subsidized remote access service (regardless of mode) be designed to take passengers out to, and bring them in from, the closest convenient point where transfer can be made to a commercial unsubsidized carrier; and

(c) subsidies and their purpose be open to public scrutiny. **Recommendation 12.5**

In the case of constitutionally provided ferry services, we recommend that:

- The federal government strive for the highest degree of cost-recovery, consistent with its constitutional obligations, or offer the affected province a grant instead of a subsidy. **Recommendation 14.2**

## THE SYSTEM COSTS

We have discussed the changes that our recommendations will bring to travellers, carriers, providers of transportation infrastructure and governments.

Since a large part of these discussions focussed on changes in costs and charges, it is important for us to talk about the general costs of the passenger transportation system today and what they will be in the future, after our recommendations are implemented.

We have demonstrated what the costs of the system are today in Tables 2(a) and 2(b), "Illustrative system-wide annual costs of inter-city domestic travel, paid by users and others, 1991, in 1991 dollars." These tables are interpreted in *Directions*, Volume 1, Chapter 3.

Chapter 18 of *Directions*, Volume 1 picks up the discussion and illustrates, by the use of tables and charts, how these estimated costs might evolve if the status quo were maintained, and how they will change after the implementation of our recommendations. Tables 4, 5 and 6 reproduce some of this information.

*Table 4*

## ILLUSTRATIVE SYSTEM-WIDE ANNUAL COSTS OF INTERCITY DOMESTIC TRAVEL IN 2000 "STATUS QUO"

Totals: $ millions, in 1991 dollars

| Type of cost | Car<br>(270 billion pass-km) | | | Bus<br>(3.3 billion pass-km) | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 0 | 5,769 | 5,769 | 0 | 10 | 10 |
| Environmental | 0 | 1,247 | 1,247 | 0 | 8 | 8 |
| Accident | 9,213 | 202 | 9,415 | 12 | 0 | 12 |
| Special trans. tax/fee | 3,199 | −3,199 | 0 | 9 | −9 | 0 |

| Vehicle/Carrier | 4,127 | 0 | 4,127 | 99 | 435 | 534 |
| **Total** | **5,048** | **802** | **5,850** | **153** | **438** | **591** |
| **Type of cost** | **Ferry<br>(1.1 billion pass-km)** | | | **All intercity travel<br>(310 billion pass-km)** | | |
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 0 | 52 | 52 | 768 | 6,532 | 7,300 |
| Environmental | 0 | 22 | 22 | 0 | 1,552 | 1,552 |
| Accident | 1 | 0 | 1 | 9,262 | 202 | 9,464 |
| Special trans. tax/fee | 10 | −10 | 0 | 3,389 | −3,389 | 0 |
| Vehicle/Carrier | 264 | 113 | 377 | 33,721 | 556 | 34,277 |
| **Total** | **275** | **177** | **452** | **47,140** | **5,453** | **52,593** |

**Note: In order to illustrate smaller components, figures are shown to the nearest $ million. In general, cost estimates are not accurate to this level of precision.**

### Table 5

## Illustrative System-Wide Annual Costs of Intercity Domestic Travel in 2000 "Directions"

**Totals: $ millions, in 1991 dollars**

| Type of cost | Car (270 billion pass-km) | | | Bus (3.3 billion pass-km) | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 5,491 | 0 | 5,491 | 9 | 0 | 9 |
| Environmental | 1,122 | 0 | 1,122 | 6 | 0 | 6 |
| Accident | 9,414 | 0 | 9,414 | 12 | 0 | 12 |
| Special trans. tax/fee | 0 | 0 | 0 | 0 | 0 | 0 |
| Vehicle/Carrier | 28,480 | 0 | 28,480 | 237 | 5 | 242 |
| **Total** | **44,507** | **0** | **44,507** | **264** | **5** | **269** |

| Type of cost | Airplane (33 billion pass-km) | | | Train (0.7 billion pass-km) | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 1,133 | 40 | 1,173 | 32 | 0 | 32 |
| Environmental | 253 | 0 | 253 | 4 | 0 | 4 |
| Accident | 33 | 0 | 33 | 1 | 0 | 1 |
| Special trans. tax/fee | 0 | 0 | 0 | 0 | 0 | 0 |
| Vehicle/Carrier | 4,127 | 0 | 4,127 | 181 | 60 | 241 |
| **Total** | **5,546** | **40** | **5,586** | **218** | **60** | **278** |

| Type of cost | Ferry (1.1 billion pass-km) | | | All intercity travel (310 billion pass-km) | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 47 | 0 | 47 | 6,725 | 40 | 6,765 |
| Environmental | 17 | 0 | 17 | 1,405 | 0 | 1,405 |
| Accident | 1 | 0 | 1 | 9,470 | 0 | 9,470 |
| Special trans. tax/fee | 0 | 0 | 0 | 0 | 0 | 0 |
| Vehicle/Carrier | 320 | 28 | 348 | 33,411 | 93 | 33,504 |
| **Total** | **385** | **28** | **413** | **51,011** | **133** | **51,144** |

Note: In order to illustrate smaller components, figures are shown to the nearest $ million. In general, cost estimates are not accurate to this level of precision.

Costs for means of travel do not sum to costs for all intercity travel, as the latter also includes allowance for costs of increased car, bus and airplane travel to replace assumed reduction in rail travel between 2000 S-Q and 2000 D cases.

Table 6

## ILLUSTRATIVE SYSTEM-WIDE ANNUAL COSTS OF INTERCITY DOMESTIC TRAVEL, CHANGES BROUGHT BY IMPLEMENTING "DIRECTIONS" COMPARED WITH THE "STATUS QUO"

Totals: $ millions, in 1991 dollars

| Type of cost | Car | | | Bus | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 5,491 | -5,769 | -278 | 9 | -10 | -1 |
| Environmental | 1,122 | -1,247 | -125 | 6 | -8 | -2 |
| Accident | 201 | -202 | -1 | 0 | 0 | 0 |
| Special trans. tax/fee | -3,199 | 3,199 | 0 | -9 | 9 | 0 |
| Vehicle/Carrier | -474 | 0 | -474 | -40 | -3 | -43 |
| **Total** | **3,141** | **-4,019** | **-878** | **-34** | **-12** | **-46** |

| Type of cost | Airplane | | | Train | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 410 | -661 | -251 | -13 | 0 | -13 |
| Environmental | 253 | -266 | -13 | 4 | -9 | -5 |
| Accident | 0 | 0 | 0 | -2 | 0 | -2 |
| Special trans. tax/fee | -165 | 165 | 0 | -6 | 6 | 0 |
| Vehicle/Carrier | 0 | 0 | 0 | 82 | -375 | -293 |
| **Total** | **498** | **-762** | **-264** | **65** | **-378** | **-313** |

| Type of cost | Ferry | | | All intercity travel | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 47 | -52 | -5 | 5,957 | -6,492 | -535 |
| Environmental | 17 | -22 | -5 | 1,405 | -1,552 | -147 |
| Accident | 0 | 0 | 0 | 208 | -202 | 6 |
| Special trans. tax/fee | -10 | 10 | 0 | -3,389 | 3,389 | 0 |
| Vehicle/Carrier | 56 | -85 | -29 | -310 | -463 | -773 |
| **Total** | **110** | **-149** | **-39** | **3,871** | **-5,320** | **-1,449** |

**Note:** In order to illustrate smaller components, figures are shown to the nearest $ million. In general, cost estimates are not accurate to this level of precision.

Costs for means of travel do not sum to costs for all intercity travel, as the latter also includes allowance for costs of increased car, bus and airplane travel to replace assumed reduction in rail travel between 2000 S-Q and 2000 D cases.

Therefore, with our recommendations in place, there will be not only a transfer of costs from taxpayers to travellers, but also annual savings for both in most types of passenger transportation costs:

| | |
|---|---|
| • savings to general taxpayers and general public | $5.320 billion |
| • increased costs to travellers | $3.871 billion |
| • savings in total costs of passenger travel | $1.449 billion |

## MEETING OUR PASSENGER TRANSPORTATION OBJECTIVES

We believe that our recommendations will meet our objectives and create a passenger transportation system that is safe, that is more protective of the environment, that ensures fairness to taxpayers, travellers and carriers and that operates more efficiently.

### Objective 1: Improving safety

We are convinced that when travellers and carriers face the full costs of accidents and safety programs, they will change their behaviour and reduce accidents. We also expect that the discipline involved in objectively assessing risks, evaluating safety measures, and providing accountability and transparency in setting charges will encourage governments to treat the modes with greater consistency, thereby getting the most safety improvement per dollar spent.

### Objective 2: Greater protection of the environment

We believe that our recommendations will lead to a greater protection of the environment by persuading users to reduce the amount of damage they cause and by ensuring that those who travel less will not pay the environmental costs imposed by those who travel more. All of the modes will be subject to the same regulatory standards and charges.

While our recommendations call for radical change, we believe they are rational, fair and will achieve national environmental goals efficiently and at a lower overall cost.

### Objective 3: Greater fairness to taxpayers, travellers and carriers

We believe that subsidies from taxpayers and some transportation users to certain groups are unfair; for example, air travellers being supported by non-travellers for the costs of air navigation systems and airport expenses or train travellers being supported by direct subsidies from taxpayers for their ticket. Such subsidies to one mode are unfair to other modes that could offer competing services.

The remedy is straightforward. Under our framework, carriers, and ultimately travellers, will pay all the costs of transportation infrastructure and services. This remedy will also apply to those modes that receive large subsidies — the passenger rail services and ferry services for which there are no constitutional obligations.

### Objective 4: A more efficient transportation system

The passenger transportation system will be made more efficient, delivering better service at lower costs, through reforms in ownership, management, pricing policies and investments.

We are convinced that competition will spur innovation: competition among modes, among carriers within modes and, where relevant, among providers of infrastructure.

## REACHING OUR DESTINATION

Our principles will ensure a framework in which costs are reflected in prices paid by travellers, and in which institutions are flexible and responsive. This framework will constrain transportation activities that become too costly relative to benefits provided, and will encourage the transportation industry to take advantage of new opportunities resulting from improved technology and other favourable developments.

This summary is only a glimpse of our findings and recommendations and we encourage you to consult *Directions*, our final report. We believe that an understanding of how the current passenger transportation system operates, how it is financed, who pays for the services and who owns and manages the system, will convince you that it is time for change.

# LE RAPPORT FINAL DE LA COMMISSION ROYALE SUR LE TRANSPORT DES VOYAGEURS AU CANADA

## RÉSUMÉ

La Commission royale sur le transport des voyageurs au Canada sait que le transport touche la vie de chacun et qu'il importe que le plus grand nombre de Canadiens soient renseignés sur nos recommandations visant le système canadien de transport des voyageurs au XXI$^{e}$ siècle.

C'est pourquoi la Commission royale a choisi de publier un résumé de son rapport final, Directions. Celui-ci donne un bref aperçu de nos principales conclusions et recommandations et nous espérons qu'il convaincra le lecteur de l'intérêt de prendre connaissance du tableau d'ensemble en lisant le rapport final.

*Directions, le Rapport final de la Commission royale sur le transport des voyageurs au Canada,* publié en quatre volumes, est disponible dans les bibliothèques municipales. Ceux et celles que cela intéresse peuvent également l'acheter directement auprès de Groupe Communication Canada — Édition, Approvisionnements et Services Canada et d'autres librairies. Pour savoir comment vous procurer le jeu complet en quatre volumes de *Directions,* ou seulement les volumes 1 et 2 (Conclusions et recommandations et documentation d'appui), vous êtes priés d'appeler le (819) 956-4802.

Les coûts à l'échelle du système 32

RÉALISER NOS OBJECTIFS EN MATIÈRE DE TRANSPORT DES VOYAGEURS 36

LE BOUT DU CHEMIN 38

# CE QUE LE GOUVERNEMENT DU CANADA AVAIT DEMANDÉ À LA COMMISSION ROYALE DE FAIRE

Partout dans le monde, le transport subit de profondes et rapides transformations. De nombreux pays mettent à l'essai de nouveaux moyens de financer l'infrastructure de transport et d'offrir sur le marché des services de transport aux voyageurs. Le desserrement des contraintes réglementaires qui pesaient sur les prestations de services de transport des voyageurs a fait surgir de nouvelles façons de répondre aux besoins des voyageurs.

Ces mutations sont loin d'être achevées et les Canadiens ne peuvent ignorer les changements qui surviennent ailleurs dans le monde et les défis qu'ils représentent. Au fur et à mesure que les économies nationales deviendront plus interdépendantes, les choix que feront les Canadiens en matière de projets et d'investissements dans le secteur du transport des voyageurs détermineront de plus en plus la réussite économique du Canada sur le marché mondial. Voilà pourquoi il importe de prendre dès aujourd'hui les bonnes décisions.

En 1990, les Canadiens ont consacré sensiblement plus de ressources au transport (16 pour cent du produit intérieur brut (PIB) qu'aux soins de santé (9 pour cent du PIB)). Selon nos estimations, en 1991, les Canadiens ont dépensé entre 30 et 45 milliards de dollars, soit une moyenne de 1 100 $ à 1 700 $ par personne, pour le transport interurbain des voyageurs.

Le Canada a considérablement changé depuis que la Commission royale MacPherson publiait son rapport il y a 30 ans. Nous croyons que le moment est venu d'élaborer un nouveau cadre pour le système canadien de transport des voyageurs, cadre qui permettra de répondre aux besoins des Canadiens au XXI$^{e}$ siècle.

La Commission royale sur le transport des voyageurs au Canada a été créée le 19 octobre 1989, en vertu de la Partie I de la *Loi sur les enquêtes*, et s'est vu accorder trois années «. . . pour faire enquête et rapport sur un système national intégré de transport interurbain des voyageurs permettant de répondre aux besoins du Canada et des Canadiens au XXI$^e$ siècle. . .»

## COMMENT LA COMMISSION ROYALE A PROCÉDÉ

Avant de formuler des recommandations pour le futur, il importait de comprendre parfaitement le système de transport des voyageurs tel qu'il existe à l'heure actuelle. Pour ce faire, la Commission royale a entrepris trois principales initiatives : nous avons consulté les Canadiens, étudié le transport des voyageurs à l'étranger et réalisé un programme de recherche.

### CONSULTATION DES CANADIENS

Nous avons mis en oeuvre toute une série de moyens — audiences publiques tenues partout au pays, mémoires écrits, télémémoires, réunions et séminaires — pour prendre l'avis des Canadiens intéressés, tant voyageurs et fournisseurs d'infrastructure et de services de transport que gouvernements, contribuables, syndicats, offices de réglementation et groupes d'intérêt spécial, représentant, par exemple, les personnes handicapées et les personnes du troisième âge. Le gros de ce que les Canadiens nous ont dit est exposé dans notre rapport intérimaire, *En marche*.

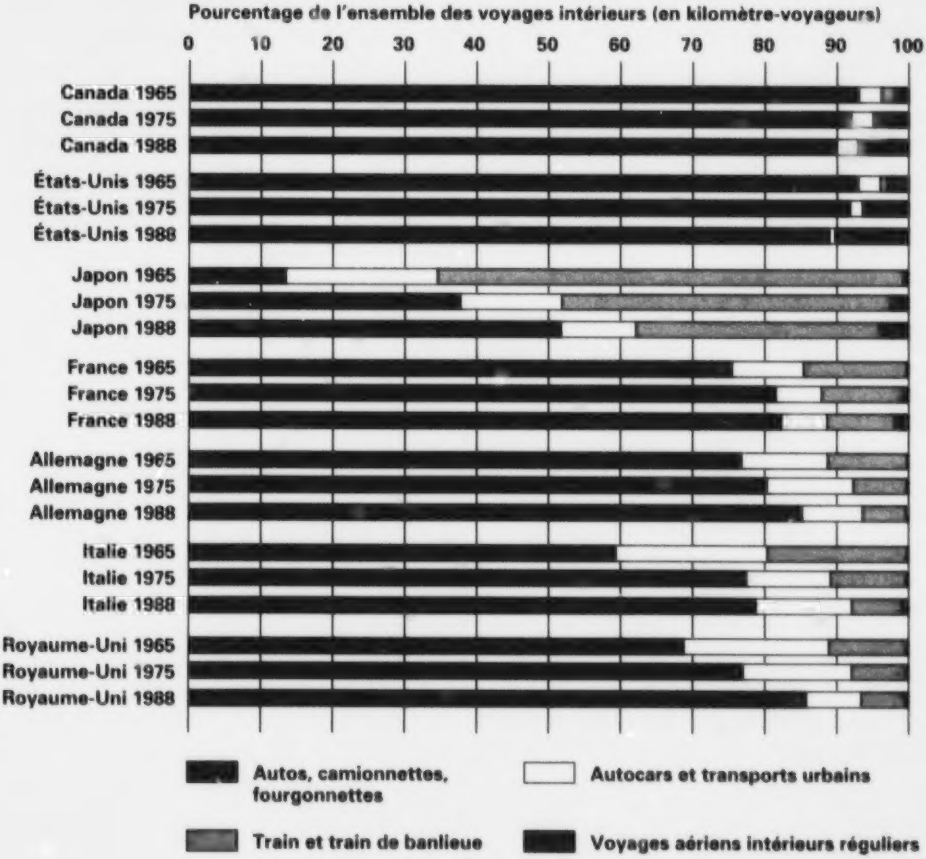
### EXAMEN DES SYSTÈMES DE TRANSPORT DES VOYAGEURS D'AUTRES PAYS

Nous nous sommes également penchés sur la façon dont d'autres pays abordent le dossier du transport des voyageurs. Nous avons découvert que le Canada n'est pas seul à remettre en question les façons traditionnelles de formuler la politique de transport et de prendre les décisions d'investissement, ni à rechercher des solutions nouvelles. Partout dans le monde, les pouvoirs publics s'attachent à rendre leurs systèmes de transport plus performants.

Les habitudes de déplacement des Canadiens sont très semblables à celles des habitants de tous les autres pays développés, même s'il existe certaines différences. La figure qui suit montre que les Canadiens, comme les voyageurs d'autres pays développés, sont très attachés à leur automobile. Le train est un mode de transport des

*Figure 1*

*COMPARAISONS AVEC D'AUTRES PAYS DES PARTS MODALES POUR L'ENSEMBLE DES VOYAGES INTÉRIEURS, 1965, 1975 ET 1988*



**Sources :** Les calculs effectués par le personnel de la Commission sont basés sur les données de Statistique Canada, de la Conférence européenne des ministres des Transports (CEMT) et d'un certain nombre de sources américaines et japonaises. Pour plus de détails, consulter les Notes relatives au chapitre 2 du volume 2 du rapport.

**Nota :** L'ensemble des voyages intérieurs comprend les voyages interurbains et urbains.

voyageurs nettement plus important au Japon, et légèrement plus important en Europe occidentale qu'au Canada ou aux États-Unis. La plupart des pays enregistrent toutefois le même déclin à long terme du train et de l'autocar qu'au Canada. L'avion a quant à lui gagné du terrain partout dans le monde. Vu la grandeur de leurs territoires respectifs, le Canada et les États-Unis comptent beaucoup plus sur l'avion que le Japon ou l'Europe occidentale.

Plusieurs pays ont récemment entrepris des études d'envergure sur le transport et certains en sont déjà au stade de l'exécution de changements. D'autres ont assoupli leur tutelle administrative et économique sur les entreprises de transport des voyageurs. Certains ont examiné des moyens de fixer les prix d'une manière qui reflète le coût véritable des services et de l'infrastructure de transport, tandis que d'autres ont mis à l'essai des modalités administratives et des structures de propriété novatrices.

## NOTRE RECHERCHE SUR LE TRANSPORT INTERURBAIN DES VOYAGEURS

Dans le cadre de notre programme de recherche, nous nous sommes penchés, entre autres, sur :

- la façon dont les Canadiens se déplacent;
- les coûts et leur prise en charge;
- l'incidence des transports sur l'environnement;
- la sécurité de chaque mode; et
- l'accès pour les personnes handicapées.

Nous avons conclu que la manière dont le système de transport est géré au Canada n'est plus adaptée au monde d'aujourd'hui. Pourquoi?

- La plupart des voyageurs ne paient pas le plein coût de leurs déplacements et les prix ne reflètent pas l'usage fait du système par le voyageur;

- Dans aucun des modes, les tarifs, redevances et droits ne couvrent pleinement les frais;
- Les transporteurs individuels sont soumis à des règles et règlements variables;
- Les coûts sont trop élevés parce que les pouvoirs publics n'investissent pas toujours dans les réalisations les plus rentables;
- Les coûts sociaux des transports, et notamment le coût écologique, ne sont presque jamais pris en compte; et
- Les contribuables sont mal renseignés sur les raisons de décisions particulières et sur l'emploi qui est fait de leur argent.

## NOTRE DÉMARCHE

### NOTRE PRINCIPE DIRECTEUR

Si un système de transport des voyageurs largement subventionné par les contribuables a été approprié pour le Canada au cours des 125 dernières années, un tel système n'est pas le bon pour le pays au seuil du XXI$^{e}$ siècle. Aujourd'hui et dans les décennies à venir, ce qu'il faut au Canada, c'est un système qui soit financé par les voyageurs qui l'utilisent et non pas qui repose sur des subventions, des services gouvernementaux et un contrôle centralisé. Le transport des voyageurs devrait être traité comme une activité commerciale.

Au lieu que ce soit les pouvoirs publics qui décident qui peut transporter des passagers, nous croyons que ce qu'il faut, c'est un système régi par le marché. Au lieu que les pouvoirs publics fournissent le gros de l'infrastructure, nous pensons que cela devrait revenir au marché, les premiers se limitant aux rôles d'arbitre et décideurs. Au fur et à mesure que l'on abandonne une tutelle centralisée et souvent éloignée, nous pensons que les responsabilités en matière de transport devraient être confiées au niveau de gouvernement le plus proche de la population et le mieux à même de s'en acquitter efficacement.

Jusqu'à présent, le système de transport des voyageurs a été principalement soutenu financièrement par les contribuables, dont bon nombre ne voyagent que très peu, ou pas du tout. Nous pensons qu'il devrait maintenant s'autofinancer de façon à ce que les voyageurs paient ce qu'ils consomment et en aient pour leur argent.

## NOTRE MÉTHODE : UN CADRE DE RÉFÉRENCE

La Commission royale a examiné le système de transport des voyageurs dans son ensemble. Nous cherchions à résoudre non seulement les questions et problèmes d'aujourd'hui, mais également ceux de demain.

Pour ce faire, nous avons adopté une méthode devant déboucher sur l'établissement d'un cadre de référence à long terme pour le transport des voyageurs. Qu'entendons-nous par «cadre de référence»? Nous entendons par là les lois, règlements et institutions qui régissent les transports.

Trop souvent, les décisions en matière de transport des voyageurs sont incohérentes, à court terme et coûteuses. Une fois en place le cadre de référence que nous prônons, les décisions futures seront logiques, cohérentes et moins onéreuses; une fois comptabilisés les coûts défrayés par toutes les parties.

## NOS ORIENTATIONS : BUT ET OBJECTIFS DU SYSTÈME DE TRANSPORT

Pour jeter les bases de ce nouveau cadre, la Commission royale a défini un but pour le transport des voyageurs et quatre objectifs sur lesquels les Canadiens s'entendent et qui devraient, selon nous, guider le Canada à l'avenir. Nous proposons des solutions canadiennes à des problèmes canadiens.

Nous croyons que le système de transport interurbain des voyageurs au Canada doit poursuivre un but : emmener les gens là où ils veulent aller. Les voyageurs devraient pouvoir choisir les services de transport qu'ils veulent, en payer le prix et en avoir pour leur argent. Ils ne devraient pas être encouragés à se rendre à certains endroits ou à recourir à des modes particuliers par des politiques gouvernementales ou des subventions qui favorisent des destinations ou des modes précis.

Nous recommandons que le système de transport des voyageurs soit guidé par les quatre objectifs suivants :

a) la sécurité;

b) la protection de l'environnement;

c) l'équité envers les contribuables, les voyageurs et les transporteurs; et

d) l'efficience, de telle façon que les services soient assurés uniquement si les avantages qu'ils apportent aux voyageurs individuels en égalent ou excèdent le coût et que des niveaux donnés de service soient fournis au moindre coût possible.
**Recommandation 4.1**

Qu'en est-il d'autres objectifs possibles du système de transport des voyageurs, comme par exemple l'édification nationale et l'expansion économique régionale? Lors des audiences publiques tenues par la Commission royale, certains Canadiens nous ont entretenu de l'importance du transport des voyageurs pour l'édification du pays et le développement régional. L'édification de la nation et le développement régional devraient être des objectifs des différents paliers de gouvernement, mais devrait-il s'agir d'objectifs à poursuivre grâce au transport des voyageurs? Nous pensons que non. Les politiques en matière de transport des voyageurs ne devraient pas être guidées par les objectifs d'édification de la nation et d'expansion économique régionale pour les raisons qui suivent.

*Édification de la nation :* De manière générale, le système de transport des voyageurs est parvenu à maturité, et la plupart des Canadiens sont bien desservis par les divers modes. Nous pensons qu'aucun projet, qu'aucune route, qu'aucun réseau ou mode n'est susceptible aujourd'hui de devenir un symbole national unificateur, comme ce fut le cas jadis du chemin de fer transcontinental. Nous doutons que quelque nouveau mégaprojet de transport des voyageurs puisse contribuer à l'édification de la nation, au-delà de son utilité économique, qui peut être évaluée selon les critères que nous recommandons.

*Expansion économique régionale :* Nous reconnaissons que l'infrastructure et les services de transport des voyageurs peuvent jouer un rôle vital dans le développement et le fonctionnement des économies nationales et régionales. Nous avons cependant tiré de nos recherches et de nos consultations la conclusion que les avantages distincts et supplémentaires qui pourraient en résulter sur le plan du développement régional n'ont guère de chances d'être substantiels et qu'il n'y a donc pas lieu d'aligner les politiques de transport des voyageurs sur ces seules considérations.

En conséquence, nous recommandons :

- Que les pouvoirs publics poursuivent les objectifs d'édification de la nation et d'expansion économique régionale au moyen d'autres programmes, plutôt que par le biais du système de transport des voyageurs.
  **Recommandation 4.2**

## QUELLE INCIDENCE NOS RECOMMANDATIONS AURONT-ELLES SUR LES VOYAGEURS?

**Les voyageurs devraient payer les coûts véritables des services de transport qu'ils utilisent, y compris les coûts des dommages causés à l'environnement, et les sédentaires ne devraient pas avoir à payer pour ceux qui voyagent.**

Les contribuables ne subventionneront plus les voyageurs, comme ils le font à l'heure actuelle.

Nous recommandons :

- Que chaque voyageur paie le coût intégral de son déplacement et que les voyageurs dans leur ensemble assument le plein coût du système, y compris les coûts liés à la protection de l'environnement, à la sécurité et aux accidents.
  **Recommandation 4.3**

Certains voyageurs canadiens n'apprécieront sans doute pas que nous recommandions qu'ils se voient imposer des droits et des redevances de transport. Il importe de souligner qu'à l'heure actuelle les coûts du transport des voyageurs sont couverts soit par les tarifs, soit par des taxes et par l'impôt sur le revenu. Nous pensons tout simplement que le système de transport serait plus juste pour tout le monde si le fardeau financier était déplacé de ceux qui ne l'utilisent pas à ceux qui l'utilisent.

**À l'heure actuelle, les contribuables financent sciemment les transports au moyen de subventions directes et ils les financent à leur insu au moyen de subventions cachées.**

Les subventions directes sont celles qui figurent en tant que montants transférés des contribuables aux transporteurs et aux voyageurs dans les budgets établis par les gouvernements. Les subventions cachées sont celles qui sont moins visibles du fait qu'elles ne figurent pas dans les comptes des pouvoirs publics.

Selon le schéma que nous proposons, voyageurs et transporteurs paieront l'intégralité des coûts, mais ceux-ci seront établis dans un contexte de principes d'investissement et de tarification efficients. Les voyageurs ne paieront pas un système de transport trop coûteux et gaspilleur parce qu'il est doté d'une capacité ou trop grande ou trop petite, inadaptée ou située au mauvais endroit. Voyageurs et transporteurs pourront acheter les services dont ils ont besoin au plus bas prix possible.

Le tableau 1 donne une vue d'ensemble des éléments du système de transport interurbain des voyageurs.

*Tableau 1*
*ÉLÉMENTS DU SYSTÈME DE TRANSPORT*

| **Mode** | **Transporteur** | **Infrastructure** | | |
|---|---|---|---|---|
| | | **Terminaux** | **Liens** | **Contrôle de la circulation** |
| **Routier** | Automobiles | Terrains de stationnement | Routes (ponts compris) | Police, signalisations routières, code de la route et règlements |
| | Autocars | Gares routières | | |
| **Aérien** | Avions | Aéroports (pistes comprises) | Systèmes de navigation aérienne | Contrôle de la circulation aérienne |
| **Ferroviaire** | Trains | Gares ferroviaires | Voies ferrées | Répartition, systèmes de signalisation |
| **Maritime** | Traversiers | Terminaux portuaires (y compris quais et embarcadères) | Voies navigables et canaux (y compris les aides à la navigation) | Contrôle de la circulation maritime |

Les tableaux 2(a) et 2(b) illustrent les coûts à l'échelle du système des voyages interurbains intérieurs et la part qui revient à chacun. Dans la rubrique «usagers», les tableaux donnent des estimations des coûts payés par les voyageurs et des coûts payés par les transporteurs qui seront répercutés sur les voyageurs.

Sous la rubrique «autres», les tableaux donnent les coûts qui ne reviennent pas aux voyageurs. Il s'agit, pour la plupart, de coûts qui sont payés par les contribuables, mais y figurent également des estimations des dommages environnementaux qui sont à l'heure actuelle payés par le public. Les coûts payés pas les autres représentent une mesure d'ensemble des subventions aux voyageurs.

Les tableaux montrent que c'est le transport par autocar qui est le moins coûteux, son coût total moyen se chiffrant à 9,5¢ par kilomètre-voyageur. Selon nos estimations, les voyageurs paient tout sauf 0,4¢ par kilomètre-voyageur. Les personnes qui se déplacent en voiture et en avion reçoivent une subvention totale sensiblement supérieure. En effet, les contribuables et le public subventionnent les déplacements en voiture à raison d'environ 1,8¢ par kilomètre-voyageur et les déplacements aériens de 3,6¢ par kilomètre-voyageur. Ces subventions couvrent les coûts d'infrastructure, environnementaux et d'accidents qui ne sont pas payés par les usagers, ainsi que certaines petites subventions directes versées au transport aérien dans certaines provinces, moins les taxes spéciales perçues par les gouvernements fédéral ou provinciaux.

| **Total** | **213** | **148** | **361** | **38 143** | **4 978** | **43 121** |

**Nota :** **Pour faire ressortir les composantes plus petites, les moyennes ont été arrondies au dixième de cent le plus près et les totaux au million de dollars le plus près. De façon générale, les estimations de côuts sont approximatives et ne sont pas exactes à ce niveau de précision.**

C'est pour le train et le traversier que l'on enregistre les plus grands écarts entre les coûts pour les «usagers» et les «coûts totaux», soit 33¢ par kilomètre-voyageur pour le train et 17,4¢ par kilomètre-voyageur pour le traversier. Cela est en grande partie attribuable aux importantes subventions directes versées par les contribuables aux voyageurs qui utilisent le train et certains services de traversier. Pour une interprétation de ces tableaux, voir *Directions*, volume 1, chapitre 3.

Notre recommandation selon laquelle les voyageurs devraient payer l'intégralité du coût de leur transport signifie que ceux qui recourent à un mode de transport public, par exemple l'autocar, le train, l'avion commercial ou le traversier, ainsi que ceux qui se déplacent en voiture ou en avion privé, paieraient des tarifs, des droits ou des redevances suffisants pour couvrir leur part du plein coût de la prestation des services qu'ils utilisent. Cette recommandation signifie également que le fardeau qui revient aux contribuables serait réduit en conséquence.

Si les voyageurs devaient payer l'intégralité du coût de leurs déplacements, ils paieraient également, au moyen soit d'un pourcentage du prix de leur billet, soit d'une taxe ou d'une redevance, tout dommage environnemental causé par eux et tous les coûts relatifs à la sécurité et aux accidents occasionnés par leurs déplacements.

Les redevances pour dommages environnementaux sont traitées dans les **Recommandations 7.4** et **7.5** et devront couvrir, entre autres choses, les coûts de nettoyage et d'atténuation des impacts ainsi que celui de l'administration des politiques et règlements. La **Recommandation 7.6** stipule, quant à elle, que les redevances devront s'appliquer de façon égale à tous les modes.

Pour des explications plus détaillées sur l'environnement et le texte intégral des Recommandations 7.1 à 7.7, voir *Directions*, volume 1, chapitre 7.

Les redevances correspondant aux coûts de sécurité et d'accidents devront englober le coût des services de sécurité assurés par les pouvoirs publics et les coûts de soins de santé qui reviennent à l'heure actuelle au régime d'assurance-maladie.

**Recommandation 8.1**

Pour des renseignements plus complets sur la sécurité et le texte intégral des Recommandations 8.1 et 8.2, voir *Directions*, volume 1, chapitre 8.

## L'accès des personnes handicapées au transport

Près de 10 pour cent des personnes handicapées adultes au sein de la population canadienne ont des déficiences handicapantes pour le transport. Le tableau qui suit donne une estimation du nombre de Canadiens ayant une déficience handicapante pour le transport, par type de déficience.

**Les personnes handicapées devraient bénéficier d'un meilleur accès au système de transport des voyageurs.**

*Tableau 3*

*NOMBRE DE PERSONNES AYANT UNE DÉFICIENCE HANDICAPANTE POUR LE TRANSPORT, PAR TYPE DE DÉFICIENCE, 1990*

| | Nombre | Pourcentage[a] |
|---|---|---|
| Tous les Canadiens de 15 ans et plus ayant une déficience handicapante pour le transport | 1 879 615 | 100,0 |
| Déficience mentale | 714 398 | 38,0 |
| Déficience auditive | 648 780 | 34,5 |
| Déficience visuelle | 417 990 | 22,2 |
| Déficience vocale | 159 843 | 8,5 |
| Déficience motrice (fauteuil roulant ou déambulateur) | 132 660 | 7,1 |
| Cécité | 42 176 | 2,2 |
| Déficience non précisée | 37 052 | 2,0 |

**Sources : Hickling Corporation, chiffres tirés de l'Enquête sur la santé et les limitations d'activités de Statistique Canada, 1987 avec projections jusqu'en 1990; *Transportation for People with Disabilities: A Policy Review and Analysis*, rapport rédigé à l'intention de la Commission royale sur le transport des voyageurs au Canada, RR-01, mars 1991, p. 5.**

**[a] Les pourcentages totalisent plus de 100 car certaines personnes ont plusieurs déficiences. Les chiffres comprennent les personnes résidant dans des établissements mais non celles confinées à la maison (environ 37 600).**

S'il est vrai que les pouvoirs publics et le secteur privé ont déjà beaucoup fait pour donner aux personnes handicapées l'accès aux services de transport interurbain, notre démarche va plus loin. Nous recommandons :

- Que les voyageurs ayant des déficiences physiques ou mentales jouissent de possibilités similaires d'emprunter les moyens de transport en commun que tous les Canadiens.
  **Recommandation 4.4**

Nous recommandons par ailleurs :

Que les pouvoirs publics se fixent pour objectif de donner à tous les voyageurs du Canada l'accès au transport public dans des conditions de sécurité, de confort raisonnable et de dignité, quelles que soient leurs déficiences physiques ou mentales.
**Recommandation 9.1**

En ce qui concerne les transporteurs et fournisseurs d'infrastructure, nous recommandons : qu'ils veillent dès aujourd'hui à ce que leurs spécifications pour les équipements et installations offrent aux personnes handicapées des améliorations continues de l'accessibilité; qu'ils paient le passage d'un accompagnateur s'ils décident, pour des raisons de sécurité, qu'un accompagnateur est nécessaire; et qu'ils veillent à ce que le personnel en contact avec les voyageurs handicapés possède la formation voulue pour les traiter avec sensibilité et compréhension.
**Recommandations 9.3, 9.8 et 9.9**

Nous recommandons également un rôle élargi pour l'Office national des transports (ONT) en ce qui concerne les personnes handicapées, et, plus précisément : que l'ONT établisse des normes nationales minimales d'accessibilité; qu'il veille plus activement à ce que les services de transport deviennent davantage accessibles aux personnes handicapées; et qu'il soit chargé d'arbitrer les différends concernant la nécessité d'un accompagnateur.
**Recommandations 9.2, 9.4 et 9.7**

Nous recommandons par ailleurs :

- Que, par concertation entre les associations représentatives des personnes handicapées, les associations de transporteurs et l'Office national des transports, soit mis sur pied un mécanisme, tel qu'un système de carte d'identification codée, afin d'indiquer rapidement au personnel des transporteurs le genre de services dont chaque voyageur handicapé a besoin, et notamment la nécessité d'un accompagnateur pour raisons de sécurité ou d'autres motifs.
  **Recommandation 9.6**

Pour plus de précisions sur l'accès des personnes handicapées aux services de transport et le texte intégral des Recommandations 9.1 à 9.11, voir *Directions*, volume 1, chapitre 9.

## QUELLE INCIDENCE NOS RECOMMANDATIONS AURONT-ELLES SUR LES TRANSPORTEURS?

**Les transporteurs de voyageurs devraient être exposés à la concurrence et aux pressions du marché de façon à devoir réagir aux préférences des consommateurs et à réduire leurs coûts, à améliorer l'efficience et à répercuter les économies qui en résultent sur les voyageurs.**

### Le transport des voyageurs au Canada et le marché

Nous recommandons :

- Que la concurrence et les forces du marché soient les principaux déterminants de services de transport viables et efficients.
  **Recommandation 4.5**

Afin que le marché puisse imposer cette discipline, les pouvoirs publics faciliteront l'entrée sur le marché de nouveaux concurrents en éliminant ou en assouplissant les restrictions. Quiconque est «prêt, apte et disposé» aura la possibilité d'offrir des services de transport des voyageurs. En outre, les nouveaux entrants auront accès sur un pied d'égalité à l'infrastructure de transport pourvu qu'ils soient disposés à payer leur part des coûts. Comme nous l'avons déjà dit, ces coûts comprennent tous ceux liés à la dégradation de l'environnement, à la sécurité et aux accidents, imposés par les voyageurs. Par ailleurs, quiconque assure des services de transport pourra les interrompre sans période d'attente excessive, mais avec un délai de préavis suffisant.

En conséquence, nous recommandons :

- Que les gouvernements fédéral, provinciaux et territoriaux modifient leur législation relative à la réglementation des autocars de manière à ramener les restrictions à l'entrée sur le marché aux seuls critères de «prêt, apte et disposé» et à ne plus exiger qu'un préavis suffisant avant l'abandon de routes et la publication des horaires et tarifs.
  **Recommandation 13.1**

- Que le gouvernement fédéral invite les transporteurs aériens canadiens à soumettre des propositions publiques pour de nouvelles routes aériennes internationales désignées, la compagnie offrant la meilleure formule se voyant accorder la liaison et les motifs de la décision étant rendus publics, et que les transporteurs aériens canadiens soient autorisés à se vendre entre eux des liaisons aériennes internationales désignées.
  **Recommandations 11.3 et 11.4**

- Que les pouvoirs publics s'abstiennent de faire toute contribution financière qui vise à assurer la survie de transporteurs aériens.
  **Recommandation 11.5**

- Que le gouvernement fédéral modifie les dispositions législatives intéressant l'accès aux voies de manière à préciser que tous les transporteurs qualifiés disposés à payer leur quote-part ont le droit d'accès à l'infrastructure ferroviaire essentielle et à l'égalité de traitement dans le transport ferroviaire.
  **Recommandation 6.7**

- Que les aéroports et les autorités municipales coopèrent pour assurer un accès illimité aux aéroports à tous les transporteurs de surface qui paient leur juste part des coûts et que les autorités fédérales accordent à tous les transporteurs de surface le libre accès aux aéroports et gares ferroviaires appartenant au gouvernement fédéral.
  **Recommandation 15.1**

- Que tous les contrats de vente ou de location relatifs à l'infrastructure de transport fédérale comprennent des dispositions obligeant l'exploitant à donner à tous les transporteurs intermodaux libre accès à cette infrastructure, sur un pied d'égalité.
  **Recommandation 15.2**

**Une exception à la règle . . .**

Aux termes des accords internationaux actuels, si une compagnie aérienne canadienne n'est plus détenue et contrôlée par des Canadiens, sa désignation en tant que «compagnie aérienne nationale» pourrait être contestée et, par voie de conséquence, sa faculté de desservir des routes internationales compromise.

Même si la Commission royale recommande qu'il n'y ait aucune restriction en matière de propriété pour les autres modes, nous faisons une exception pour les transporteurs aériens étant donné l'actuel régime de réglementation international.

En ce qui concerne la propriété des compagnies aériennes, nous recommandons :

- que le gouvernement fédéral et le gouvernement de l'Alberta modifient leur législation de façon à éliminer le plafond de 10 pour cent relatif aux avoirs individuels qui s'applique à l'heure actuelle à Air Canada et à Pacific Western Airlines (la société mère des Lignes aériennes Canadien International).
  **Recommandation 11.2**

- que le gouvernement fédéral maintienne les limites existantes applicables à la propriété et au contrôle par des étrangers de transporteurs aériens.
  **Recommandation 11.1**

- qu'advenant une situation où il ne resterait plus qu'un important transporteur aérien canadien, le gouvernement fédéral utilise son pouvoir pour annuler les limites imposées en matière de propriété et de contrôle étrangers dans le but exprès, et dans la mesure requise, de garantir la concurrence sur le marché intérieur.
  **Recommandation 11.6**

Pour plus de renseignements au sujet de la «propriété» en ce qui concerne le transport aérien, voir *Directions*, volume 1, chapitre 11.

## QUELLE INCIDENCE NOS RECOMMANDATIONS AURONT-ELLES SUR LES FOURNISSEURS D'INFRASTRUCTURE?

**Les fournisseurs d'éléments d'infrastructure de transport devraient faire payer leurs services. Ceux qui n'en tirent pas avantage ne devraient pas avoir à les payer.**

Transporteurs et voyageurs nous ont dit que si l'on va leur demander de payer le plein coût des terminaux comme les aéroports, des liens comme les routes et les voies ferrées, et des services de contrôle aérien, ils veulent être certains que ce qui est fourni correspond aux besoins, ni plus, ni moins. La Commission est d'accord et recommande :

- que les terminaux, les liens et les services de contrôle de la circulation soient tarifés individuellement, terminal par terminal, lien par lien et service par service.
  **Recommandation 4.6**

- que, lorsque la concurrence est suffisante, ou lorsque les passagers sont en bonne position pour négocier avec les fournisseurs de terminaux, de liens ou de services de contrôle de la circulation — et

pourvu que les frais de dégradation de l'environnement, de sécurité et d'accidents soient adéquatement recouvrés — on laisse la concurrence et les forces du marché déterminer les prix et les décisions d'investissement.
**Recommandation 4.7**

- que là où une réglementation est requise, elle soit conçue de telle manière que les prix et les décisions d'investissement soient similaires à ce que produiraient les forces du marché concurrentiel
**Recommandation 4.8**

## LA FIXATION DES PRIX

**Les voyageurs ne devraient payer que ce qu'ils utilisent.**

Les prix refléteront l'utilisation faite par les voyageurs ou transporteurs de chaque terminal, lien ou service de contrôle de la circulation et seront conçus de manière à n'encourager ni la surutilisation ni la sous-utilisation.

Lorsque les tarifs actuels sont inférieurs au prix de revient tout compris du service, ils seront rajustés de façon à recouvrer intégralement les coûts et de manière à minimiser la perte d'efficience.

En conséquence, nous recommandons :

- Que l'on envisage de recourir à des systèmes conventionnels de perception de péage lorsque de nouvelles routes d'accès limité sont requises, les droits de péage étant fixés de manière à couvrir la différence entre le coût total du lien routier considéré et les recettes correspondantes des taxes sur le carburant.
**Recommandation 5.6**

- Que les gouvernements provinciaux taxent les camions selon le poids et la distance dans le cadre d'un programme de financement routier d'ensemble.
**Recommandation 5.5**

- Que les exploitants des aéroports tirent leurs ressources de redevances spécifiques calculées aéroport par aéroport, plutôt que des recettes de la taxe sur le transport aérien. Les redevances payées par les voyageurs refléteront le potentiel commercial de l'aéroport et non son coût de construction.
  **Recommandations 5.1 et 5.3**

- Que l'exploitant du système de navigation aérienne se finance en faisant payer directement aux exploitants des aéronefs leur part du coût des services de navigation aérienne et de contrôle de la circulation aérienne, au moyen de redevances variables selon le type de vol, la catégorie d'aéronef et la valeur des avantages obtenus, plutôt que par le biais de la taxe sur le transport aérien. Ce système remplacerait la taxe sur le transport aérien.
  **Recommandation 5.7**

La décision de passer à la tarification lien par lien du réseau routier actuel dépendra, en partie, de la viabilité technologique, du coût administratif et de la réaction du public.

Pour les projets routiers, nous recommandons :

- Que les gouvernements provinciaux et territoriaux financent leur réseau routier et tous les travaux convenus sur le système routier national à l'intérieur de leurs frontières au moyen des taxes sur le carburant et autres redevances.
  **Recommandation 6.6**

Pour plus de détails sur l'investissement et la tarification ainsi que le texte complet des Recommandations 5.1 à 5.7, voir *Directions*, volume 1, chapitres 5 et 6.

## Investir dans le transport

**Des investissements ne seront consentis que pour les projets qui présentent pour les voyageurs des avantages supérieurs aux coûts et dans ceux qui offrent la rentabilité optimale, quel que soit le mode de transport considéré.**

En conséquence, nous recommandons :

- Qu'aux fins de la cession des aéroports à des administrations aéroportuaires locales, le gouvernement fédéral estime la valeur des installations aéroportuaires existantes en fonction du potentiel commercial de l'aéroport et non de son coût de construction.
  **Recommandation 5.3**
- Que les pouvoirs publics ou les administrations aéroportuaires locales décident des investissements ponctuellement, aéroport par aéroport, et n'en effectuent que lorsqu'ils peuvent compter que le coût, y compris un rendement sur l'investissement, sera couvert par les recettes futures.
  **Recommandations 5.1 et 5.3**
- Que les autorités provinciales et territoriales, pour déterminer l'ampleur de la rénovation et de l'amélioration du réseau routier national, se laissent guider par la comparaison des avantages et des coûts des projets individuels plutôt que par des normes techniques uniformes.
  **Recommandation 6.4**
- Que les pouvoirs publics investissent dans l'infrastructure ferroviaire à grande vitesse uniquement si les avantages à l'échelle du système de transport des voyageurs l'emportent sur les coûts et si les contribuables n'ont pas à payer de subventions d'exploitation.
  **Recommandation 12.6**
- Que toute compagnie de chemin de fer soit autorisée à abandonner une longueur illimitée de voies.
  **Recommandation 6.8**

- Que tous les organismes responsables utilisent des valeurs comparables pour les blessures et décès lorsqu'ils évaluent tout projet d'amélioration de la sécurité dans les divers modes.
  **Recommandation 8.2**

## QUELLE INCIDENCE NOS RECOMMANDATIONS AURONT-ELLES SUR LES POUVOIRS PUBLICS?

**Le transport devrait être retranché du régime fiscal et budgétaire gouvernemental et intégré à un régime qui soit financé et maintenu par les usagers du système.**

Nous avons dit que la concurrence et les forces du marché devraient être les principaux déterminants dans l'établissement d'un système viable et efficient de transport des voyageurs. Il est cependant un certain nombre de fonctions à l'intérieur du système qui ne devraient revenir qu'aux pouvoirs publics.

- Il incombera aux pouvoirs publics de formuler les politiques à l'intérieur du cadre de référence, d'arrêter et faire respecter les normes, de rassembler et disséminer l'information auprès du public, d'assurer une quantité suffisante de recherches, de préserver la concurrence et de réglementer les monopoles.
  **Recommandation 4.9**

Les ministères des Transports fédéral, provinciaux et territoriaux devraient voir leurs effectifs diminuer puisque leur rôle se limitera à la formulation des politiques. Ils devraient céder la plupart de leurs responsabilités opérationnelles. Quelques organismes publics pourront encore être appelés à fournir certains services de transport et à exploiter quelques infrastructures. Cependant, ils devront pour cela se passer de subventions, et des entreprises privées seront libres, de façon générale, de desservir ces marchés en concurrence avec eux.

En conséquence, nous recommandons :

- Que le gouvernement fédéral procède au transfert de tous les aéroports fédéraux restants à des administrations aéroportuaires locales et (ou) à d'autres exploitants locaux, et qu'il fasse passer le système de navigation aérienne du statut d'organisation ministérielle à celui de société d'État ou d'institution indépendante.
  **Recommandations 6.1 et 6.2**
- Que chaque gouvernement provincial et territorial mette sur pied une société d'État, complétée d'un organisme consultatif, afin de fournir les routes de manière plus efficiente et de rendre plus transparentes les décisions en matière de tarification et d'investissement routier.
  **Recommandation 6.3**
- Que les compagnies de chemin de fer offrent les emprises ferroviaires abandonnées, selon une procédure officielle, aux divers paliers de gouvernement puis à d'autres sociétés ferroviaires avant qu'elles puissent être converties à d'autres fins. Tous les niveaux de gouvernement se doteront de politiques, assorties de critères explicites, pour déterminer quels couloirs ils souhaitent conserver pour le transport futur et veilleront à ce que les terrains ainsi acquis restent intacts.
  **Recommandation 6.9**

Nous recommandons en outre que le gouvernement fédéral :

- Réexamine la *Loi sur la concurrence* ainsi que la politique pertinente et, au besoin, renforce les pouvoirs requis pour empêcher que des pratiques anticoncurrentielles ne s'installent dans le secteur du transport interurbain par autocar.
  **Recommandation 13.2**
- Étende sa réglementation régissant les pratiques anticoncurrentielles dans les systèmes de réservation informatisés aux modes autres que le transport aérien, dans le cadre d'une approche multimodale.
  **Recommandation 15.3**

- Fixe le régime réglementaire qui sera applicable à tout système de train à grande vitesse, y compris la réglementation sécuritaire et environnementale.
  **Recommandation 12.8**

Nous recommandons en outre que l'Office national des transports :

- Veille à ce que les couloirs ferroviaires abandonnés soient offerts aux pouvoirs publics ou à d'autres sociétés ferroviaires à un prix raisonnable.
  **Recommandation 6.9**

Nous recommandons également que les gouvernements provinciaux et territoriaux :

- Mettent en place des normes minimales plus uniformes et plus adéquates en ce qui concerne l'accessibilité des autocars interurbains par les voyageurs handicapés. À défaut, le gouvernement fédéral réassumera la responsabilité en matière de normes d'accessibilité nationales déléguée aux provinces, dans le but d'assurer une plus grande uniformité.
  **Recommandation 9.10**

Nous recommandons d'autre part que tous les pouvoirs publics :

- Améliorent les données sur les voyages et les transports à l'intention du public et que le gouvernement fédéral publie un rapport annuel sur le système de transport des voyageurs.
  **Recommandations 16.2, 16.3 et 16.4**

Nous avons conscience que les politiques d'un niveau de gouvernement portant sur un mode de son ressort peuvent entraîner des répercussions sur d'autres modes qui relèvent d'un autre palier. Néanmoins, ce genre d'interaction ne pose pas en soi de problème dès lors que tous les modes assument l'intégralité de leurs coûts.

En conséquence, nous recommandons :

- Que les pouvoirs gouvernementaux de décision soient attribués au palier de gouvernement le plus proche du public et le mieux à même de les exercer avec efficience.
  **Recommandation 4.10**

Nous pensons par ailleurs que notre cadre de référence peut être mis en place au moyen d'une démarche concertée et sans modification des modalités juridictionnelles actuelles.

En conséquence, nous recommandons :

- Que le Conseil des ministres responsables des transports et de la sécurité routière désigne un système routier national dont l'exploitation et l'entretien feront l'objet d'une action concertée des gouvernements provinciaux et territoriaux et (ou) de leurs organismes de gestion routière.
  **Recommandation 6.5**
- Que les autorités locales ou régionales assument la responsabilité des dégradations causées à l'environnement lorsque leur source et leurs effets sont locaux.
- Que le gouvernement fédéral ait compétence lorsque les retombées environnementales enjambent les limites régionales ou les frontières nationales, et qu'il continue de rechercher une entente internationale sur une stratégie efficace de lutte contre le réchauffement planétaire et de chercher à harmoniser les politiques et taxes nationales avec celles de la communauté internationale.
  **Recommandation 7.2**

## Tous les modes seront traités sur un pied d'égalité

Nous recommandons :

- Que les pouvoirs publics taxent et réglementent tous les modes sur un pied d'égalité.
  **Recommandation 4.11**

Nous recommandons :

- Que toutes les taxes sur le carburant soient utilisées aux fins du transport ou comme moyen de recouvrer les coûts engendrés par le transport, tels que les frais de dégradation de l'environnement et les dépenses de santé.
  **Recommandation 5.4**
- Que les pouvoirs publics appliquent les redevances sur les émissions de façon égale à tous les modes de transport, ainsi qu'aux sources qui ne sont pas liées au transport, selon une formule qui se rapproche le plus possible d'un calcul par unité d'émission.
  **Recommandation 7.6**
- Que les pouvoirs publics promulguent des règlements visant le contrôle efficace des émissions dommageables pour l'environnement qui imposent des obligations semblables, en coût par unité de réduction, à chaque mode, et qui traitent de la même façon les sources de polluants non liées au transport.
  **Recommandation 7.3**
- Que les pouvoirs publics distinguent clairement les revenus en provenance des redevances sur les émissions de ceux en provenance d'autres redevances de transport et qu'ils utilisent ces revenus pour pallier aux dégâts, indemniser les personnes touchées ou faire baisser l'impôt général. Ils ne devraient pas utiliser ces revenus pour l'expansion ou l'entretien du système de transport des voyageurs.
  **Recommandation 7.7**

## Amélioration de la reddition de comptes et de la transparence

**Les coûts du système de transport devraient être visibles et les pouvoirs publics devraient être tenus de rendre compte de leurs décisions.**

Les décisions en matière de transport des voyageurs faites par les pouvoirs publics devraient être claires, visibles et directes, et tous les coûts devraient être rendus publics. En conséquence, nous recommandons :

- Que la prise de décision soit transparente, de telle façon que les Canadiens comprennent les raisons des choix en matière de transport opérés par les gouvernements ou leurs organismes et que les responsables de ces décisions aient à rendre des comptes.
  **Recommandation 4.12**

Pour assurer la transparence du processus décisionnel, nous recommandons en outre :

- Que, si les organismes créés pour fournir l'infrastructure de transport en ont le monopole, le niveau de gouvernement responsable veille à créer des conseils consultatifs de voyageurs et autres intéressés afin qu'ils conseillent la direction de ces organismes quant aux priorités d'investissement, aux méthodes de tarification et aux redevances appropriées pour parvenir à l'autofinancement.
  **Recommandation 16.1**
- Que les pouvoirs publics informent le public d'une manière claire du montant et des motifs de toute subvention qui continuera d'être versée aux transporteurs.
  **Recommandations 12.5, 14.4 et 16.4**
- Que le gouvernement fédéral affecte des ressources à la collecte et à l'amélioration des données sur les voyages et les transports, que les gouvernements provinciaux, territoriaux et fédéral collaborent à cet effet, et que ces renseignements soient communiqués au public.
  **Recommandations 16.2 et 16.3**

- Que le gouvernement fédéral publie chaque année un rapport sur le système de transport des voyageurs, comprenant des renseignements sur l'utilisation des services de transport, les subventions, le recouvrement des coûts et la mesure dans laquelle les objectifs sont réalisés, de même que des données sur la fiabilité et la sécurité du système de transport des voyageurs.
  **Recommandation 16.4**

## PRÉVOIR LA TRANSITION

Nous avons conscience que le système de transport des voyageurs qui prendra forme à l'intérieur de notre cadre de référence sera différent de l'actuel système et que les gouvernements devront accorder aux voyageurs, transporteurs et fournisseurs d'installations le temps nécessaire pour s'adapter.

En conséquence, nous recommandons :

- Que dans les cas où une période transitoire est requise pour étaler les ajustements de prix ou lorsqu'un sursis est accordé à un transporteur, un service particulier d'un transporteur, un terminal ou un lien, l'aide financière soit de nature à encourager l'adaptation.
  **Recommandation 4.13**
- Si les transporteurs, services particuliers de transporteurs, terminaux ou liens ne deviennent pas viables après un délai d'adaptation raisonnable, que les services soient fermés ou interrompus.
  **Recommandation 4.14**

Pendant cette période d'adaptation, toute subvention restante financée par les contribuables sera :

- conçue, dans toute la mesure du possible, de manière à assurer le transport de la façon la plus efficiente possible, par quelque mode que ce soit;

- payée en puisant dans les recettes fiscales générales du palier de gouvernement qui prend la décision, et non par les autres usagers des transports; et
- programmée sur une période d'adaptation raisonnable et selon un barème dégressif aboutissant à zéro.
  **Recommandation 4.13**

La Commission royale reconnaît quatre cas pour lesquels les pouvoirs publics auront peut-être à verser des subventions transitoires : aéroports, transporteurs ferroviaires, autocars et traversiers. En conséquence, nous recommandons :

- Que dans les cas où l'application de nos principes aux aéroports, y compris tous les aéroports de Transports Canada, entraînerait de fortes hausses des redevances payées par les voyageurs, les pouvoirs publics offrent des subventions transitoires échelonnées sur dix ans. Le niveau initial de la subvention sera déterminé par le déficit d'exploitation actuel et servira à couvrir les dépenses d'équipement aussi bien que d'exploitation ou, si l'aéroport ferme ses portes, à d'autres fins de transport.
  **Recommandation 5.2**
- Que le gouvernement fédéral promulgue une loi donnant à VIA Rail un mandat de telle nature que la Société puisse fonctionner sur une base commerciale et établissant une disposition de temporisation sur dix ans de la subvention générale. Pendant cette période, VIA Rail disposera d'une plus grande liberté de décisions pour la direction de ses opérations, notamment en ce qui concerne l'investissement, le choix des lignes, les niveaux de service et les prix. Elle sera libre d'offrir d'autres services, sur une base concurrentielle, y compris des liaisons de banlieue et le transport de courrier, et elle sera tenue de déposer et de publier des plans d'exploitation et des rapports financiers annuels détaillés montrant les coûts et les recettes des lignes individuelles. Au bout de dix ans, toutes les lignes, exception faite des services aux régions éloignées, cesseront d'être subventionnées.
  **Recommandations 12.1, 12.2 et 12.3**

- Que, si besoin est, pour éviter de trop fortes augmentations des tarifs pratiqués par les compagnies d'autocar pour certains trajets, suite à l'assouplissement de la réglementation économique du secteur, les pouvoirs publics consentent des subventions transitoires selon un barème dégressif, étalées sur dix ans.
  **Recommandation 13.3**

- Que, si besoin est, pour éviter de trop fortes augmentations des tarifs, les pouvoirs publics versent à différents services de traversier des subventions transitoires, sur une période maximale de dix ans.
  **Recommandation 14.1**

Dans certains cas, les pouvoirs publics choisiront peut-être de maintenir les subventions à des services de transport des voyageurs qui ne sont pas viables. De telles subventions ne s'inscriraient pas dans notre cadre de référence et, de façon générale, ne devraient pas être maintenues. Cependant, si des gouvernements continuent de verser des subventions en dépit de nos recommandations, ils devront le faire de manière à ce que les services visés soient aussi efficients que possible. Par ailleurs, ce seront les contribuables, et non pas les voyageurs, qui paieront ces subventions.

Dans les cas où les pouvoirs publics jugeraient opportun de verser une subvention pour un service voyageurs à une localité isolée, nous recommandons :

a) que l'on utilise le mode et le transporteur le plus efficient et, chaque fois que cela est possible, que l'on lance un appel d'offres;

b) que toute desserte subventionnée en région isolée (quel que soit le mode) soit conçue de manière à ne transporter les voyageurs que jusqu'au point de correspondance commode le plus proche avec un service commercial non subventionné; et

c) que les subventions et leur justification soient soumises à l'examen du public.
**Recommandation 12.5**

Dans le cas de services de traversier visés par une obligation constitutionnelle, nous recommandons :

- Que le gouvernement fédéral s'efforce de recouvrer les coûts par une exploitation efficiente et une tarification optimale dans l'exécution de ses obligations constitutionnelles, ou alors qu'il offre à la province concernée une allocation tenant lieu de subvention. **Recommandation 14.2**

## Les coûts à l'échelle du système

Nous avons traité des changements que supposeront nos recommandations pour les voyageurs, les transporteurs, les fournisseurs d'infrastructure et les pouvoirs publics.

Étant donné que ce faisant nous avons été amenés à nous attarder sur des changements au niveau des coûts et des droits, il importe que nous examinions les coûts d'ensemble du système de transport des voyageurs d'aujourd'hui et de demain, une fois nos recommandations mises en oeuvre.

Les tableaux 2(a) et 2(b), «Coûts annuels des voyages interurbains intérieurs pour le système dans son ensemble, payés par les usagers et par les autres, 1991, en dollars de 1991», expliquent quels sont les coûts du système. Ces tableaux se trouvent dans le rapport *Directions*, volume 1, chapitre 3.

Le chapitre 18 de *Directions*, volume 1, reprend la discussion et illustre, grâce à des tableaux et figures, l'évolution que pourraient suivre ces coûts estimatifs si le statu quo était maintenu et la façon dont ils changeront une fois mises en oeuvre nos recommandations. Les tableaux 4, 5 et 6 reproduisent certaines de ces données.

*Tableau 4*

## ESTIMATION DES COÛTS ANNUELS DES DÉPLACEMENTS INTERURBAINS AU CANADA, SCÉNARIO STATU QUO 2000

Totaux : en millions de $, en dollars de 1991

| Types de coûts | Automobile (278 milliards de km-voy.) | | | Autocar (3,3 milliards de km-voy.) | | |
|---|---|---|---|---|---|---|
| | Usagers | Autres | Total | Usagers | Autres | Total |
| Infrastructure | 0 | 5 769 | 5 769 | 0 | 10 | 10 |
| Environnement | 0 | 1 247 | 1 247 | 0 | 8 | 8 |
| Accidents | 9 213 | 202 | 9 415 | 12 | 0 | 12 |
| Taxes/redevances spéciales | 3 199 | -3 199 | 0 | 9 | -9 | 0 |
| Véhicules/transporteurs | 28 954 | 0 | 28 954 | 277 | 8 | 285 |
| **Total** | **41 366** | **4 019** | **45 385** | **298** | **17** | **315** |

| Types de coûts | Avion (33 milliards de km-voy.) | | | Train (1,4 milliard de km-voy.) | | |
|---|---|---|---|---|---|---|
| | Usagers | Autres | Total | Usagers | Autres | Total |
| Infrastructure | 723 | 701 | 1 424 | 45 | 0 | 45 |
| Environnement | 0 | 266 | 266 | 0 | 9 | 9 |
| Accidents | 33 | 0 | 33 | 3 | 0 | 3 |
| Taxes/redevances spéciales | 165 | -165 | 0 | 6 | -6 | 0 |
| Véhicules/transporteurs | 4 127 | 0 | 4 127 | 99 | 435 | 534 |
| **Total** | **5 048** | **802** | **5 850** | **153** | **438** | **591** |

| Types de coûts | Traversier (1,1 milliard de km-voy.) | | | Voyages interurbains — Total (310 milliards de km-voy.) | | |
|---|---|---|---|---|---|---|
| | Usagers | Autres | Total | Usagers | Autres | Total |
| Infrastructure | 0 | 52 | 52 | 768 | 6 532 | 7 300 |
| Environnement | 0 | 22 | 22 | 0 | 1 552 | 1 552 |
| Accidents | 1 | 0 | 1 | 9 262 | 202 | 9 464 |
| Taxes/redevances spéciales | 10 | -10 | 0 | 3 389 | -3 389 | 0 |
| Véhicules/transporteurs | 264 | 113 | 377 | 33 721 | 556 | 34 277 |
| **Total** | **275** | **177** | **452** | **47 140** | **5 453** | **52 593** |

**Nota :** Pour faire ressortir les plus petites composantes, les chiffres sont exprimés au million de dollars le plus près. En général, les évaluations de coûts ne sont pas exactes à ce niveau de précision.

*Tableau 5*

## ESTIMATION DES COÛTS ANNUELS DES DEPLACEMENTS INTERURBAINS AU CANADA — SCENARIO «DIRECTIONS» 2000

Totaux : en millions de $, en dollars de 1991

| | **Automobile (270 milliards de km-voy.)** | | | **Autocar (3,5 milliards de km-voy.)** | | |
|---|---|---|---|---|---|---|
| **Types de coûts** | Usagers | Autres | Total | Usagers | Autres | Total |
| **Infrastructure** | 5 491 | 0 | 5 491 | 9 | 0 | 9 |

| **Accidents** | 9 414 | 0 | 9 414 | 12 | 0 | 12 |
| **Taxes/redevances spéciales** | 0 | 0 | 0 | 0 | 0 | 0 |
| **Véhicules/transporteurs** | 28 480 | 0 | 28 480 | 237 | 5 | 242 |
| **Total** | **44 507** | **0** | **44 507** | **264** | **5** | **269** |

| | **Avion (33 milliards de km-voy.)** | | | **Train (0,7 milliard de km-voy.)** | | |
|---|---|---|---|---|---|---|
| **Types de coûts** | Usagers | Autres | Total | Usagers | Autres | Total |
| **Infrastructure** | 1 133 | 40 | 1 173 | 32 | 0 | 32 |
| **Environnement** | 253 | 0 | 253 | 4 | 0 | 4 |
| **Accidents** | 33 | 0 | 33 | 1 | 0 | 1 |
| **Taxes/redevances spéciales** | 0 | 0 | 0 | 0 | 0 | 0 |
| **Véhicules/transporteurs** | 4 127 | 0 | 4 127 | 181 | 60 | 241 |
| **Total** | **5 546** | **40** | **5 586** | **218** | **60** | **278** |

| | **Traversier (1,1 milliard de km-voy.)** | | | **Voyages interurbains — total (310 milliards de km-voy.)** | | |
|---|---|---|---|---|---|---|
| **Types de coûts** | Usagers | Autres | Total | **Usagers** | **Autres** | **Total** |
| **Infrastructure** | 47 | 0 | 47 | **6 725** | **40** | **6 765** |
| **Environnement** | 17 | 0 | 17 | **1 405** | **0** | **1 405** |
| **Accidents** | 1 | 0 | 1 | **9 470** | **0** | **9 470** |
| **Taxes/redevances spéciales** | 0 | 0 | 0 | **0** | **0** | **0** |
| **Véhicules/transporteurs** | 320 | 28 | 348 | **33 411** | **93** | **33 504** |
| **Total** | **385** | **28** | **413** | **51 011** | **133** | **51 144** |

**Nota :** **Pour faire ressortir les plus petites composantes, les chiffres sont exprimés au million de dollars le plus près. En général, les évaluations de coûts ne sont pas exactes à ce niveau de précision.**

**Les coûts pour chaque moyen de transport ne correspondent pas, une fois additionnés, aux coûts de l'ensemble des voyages interurbains étant donné que le montant total comprend le coût de la multiplication des déplacements en automobile, en autocar et en avion pour remplacer la réduction des voyages ferroviaires entre les scénarios SQ 2000 et D 2000.**

*Tableau 6*

## ESTIMATION DES COÛTS ANNUELS DES DÉPLACEMENTS INTERURBAINS AU CANADA — CHANGEMENTS APPORTÉS PAR LE SCÉNARIO D 2000 PAR RAPPORT AU SCÉNARIO SQ 2000

Totaux : en millions de $, en dollars de 1991

| Types de coûts | Automobile | | | Autocar | | |
|---|---|---|---|---|---|---|

| **Total** | **110** | **–149** | **–39** | **3 871** | **–5 320** | **–1 449** |

**Nota :** Pour faire ressortir les plus petites composantes, les chiffres sont exprimés au million de dollars le plus près. En général, les évaluations de coûts ne sont pas exactes à ce niveau du précision.

Les coûts pour chaque moyen de transport ne correspondent pas, une fois additionnés, aux coûts de l'ensemble des voyages interurbains étant donné que le montant total comprend le coût de la multiplication des déplacements en automobile, en autocar et en avion pour remplacer la réduction des voyages ferroviaires entre les scénarios SQ 2000 et D 2000.

Par conséquent, une fois nos recommandations adoptées, il y aura non seulement transfert des coûts du contribuable au voyageur mais également des économies annuelles pour les deux en ce qui concerne la plupart des types de coûts de transport des voyageurs :

| | |
|---|---|
| • économie pour les contribuables et le grand public | 5,320 milliards $ |
| • augmentations des coûts pour les voyageurs | 3,871 milliards $ |
| • économies du coût total des déplacements des voyageurs | 1,449 milliard $ |

## RÉALISER NOS OBJECTIFS EN MATIÈRE DE TRANSPORT DES VOYAGEURS

Nous croyons que nos recommandations permettront l'établissement d'un système de transport des voyageurs sûr, respectueux de l'environnement, équitable à l'égard des contribuables, des usagers et des transporteurs et économiquement efficient.

**Premier objectif : une amélioration de la sécurité**

Nous sommes convaincus que lorsque voyageurs et transporteurs devront payer l'intégralité des coûts des accidents et des programmes de sécurité, ils changeront de comportement, ce qui réduira le nombre d'accidents. Nous nous attendons également à ce que la discipline requise pour faire une évaluation objective des risques et des mesures de sécurité pour assurer la reddition de comptes et la transparence dans la tarification encouragera les pouvoirs publics à traiter plus uniformément les différents modes, rentabilisant ainsi au maximum les sommes consacrées à l'amélioration de la sécurité.

**Deuxième objectif : une meilleure protection de l'environnement**

Nous croyons que nos recommandations amèneront une meilleure protection de l'environnement en convaincant les usagers de réduire les dommages qu'ils causent et en veillant à ce que ceux qui voyagent moins ne paient pas les coûts environnementaux infligés par ceux qui se déplacent plus. Tous les modes seront assujettis aux mêmes normes et redevances.

Même si nos recommandations visent des changements radicaux, nous croyons qu'elles sont rationnelles et justes et qu'elles permettront la réalisation efficiente et au moindre coût de l'ensemble des objectifs environnementaux nationaux.

**Troisième objectif : une plus grande équité envers les contribuables, les voyageurs et les transporteurs**

Nous croyons que les subventions versées par les contribuables et les usagers des transports à certains groupes de voyageurs sont injustes. Citons, à titre d'exemple, les voyageurs aériens qui bénéficient des systèmes de navigation aérienne et de services aéroportuaires financés par des non-voyageurs, et les voyageurs de train dont une partie du billet est payée à même des subventions directes versées par les contribuables. De telles subventions consenties à un mode sont injustes à l'égard des autres qui pourraient proposer des services concurrentiels.

La solution est simple. En vertu de notre cadre de référence, transporteurs et, en fin de compte, voyageurs, paieront l'intégralité des coûts de l'infrastructure et des services de transport. Cette solution s'appliquera également aux modes qui bénéficient d'importantes subventions, notamment les services ferroviaires voyageurs et les services de traversier qui ne sont visés par aucune obligation constitutionnelle.

**Quatrième objectif : un système de transport plus efficient**

Le système de transport des voyageurs sera rendu plus efficient, c'est-à-dire en mesure d'offrir un meilleur service à moindre coût, par une refonte de la structure de propriété, de la gestion, des politiques de tarification et de la prise de décisions en matière d'investissement.

Nous sommes convaincus que la concurrence encouragera l'innovation : compétition entre les modes, entre les transporteurs à l'intérieur de chaque mode et, le cas échéant, entre fournisseurs d'infrastructure.

## LE BOUT DU CHEMIN

Nos principes érigeront un cadre où les prix payés par les voyageurs refléteront les coûts et où les institutions seront flexibles et attentives. Ce cadre pénalisera les activités de transport qui deviennent trop coûteuses par rapport aux avantages qu'elles apportent et encouragera le secteur des transports à saisir les possibilités nouvelles offertes par les progrès technologiques et autres évolutions favorables.

Le présent résumé ne donne qu'un aperçu de nos conclusions et recommandations, et nous encourageons le lecteur à consulter *Directions*, notre rapport final. Nous pensons qu'une bonne connaissance de la façon dont fonctionne et est financé le système de transport des voyageurs, de son mode de gestion, de son régime de propriété et de la répartition des coûts vous convaincra qu'il est temps de changer les choses.

**TRANSMITTAL LETTER** xxi

**FOREWORD — OUR VISION** xxiii

**ACKNOWLEDGEMENTS** xxvii

**CHAPTER 1. POINT OF DEPARTURE** 1

Setting the Stage 1
  Changes in the World Community 1
  Why it is Important to Make the Right Passenger Transportation Decisions 2
  Public Concerns over Passenger Transportation 3
Our Activities 3
  Consulting with Canadians 4
  Studying Passenger Transportation in Other Countries 4
  Researching Intercity Passenger Transportation in Canada 6
Our Approach 7
  Our Method 7
  Our Directions 8
  Our Guiding Philosophy 8
  The Past and the Future 10
Moving Forward 11
Endnotes 12

---

* This Table of Contents reflects the material in Volume 1 of our report. The report consists of four volumes. Volumes 1 and 2 form the main report with Volume 2 providing additional details and technical material to support the material in Volume 1. Volumes 3 and 4 consist of a selection of research studies prepared for us under contract with their authors or by Royal Commission staff. Volumes 3 and 4 will be of interest to technical experts and are not integral to understanding our report.

**CHAPTER 2. CANADIAN PERSPECTIVES: PAST, PRESENT AND FUTURE** 13

Introduction 13
An Historical Perspective 13
  Past Roles of Government 14
  Changing Roles of Government 16
Canada's Passenger Transportation System Today 17
  Why Canadians Travel 19
  How Canadians Travel 20
Canada's Passenger Transportation System: 1992 and Beyond 27
Conclusion 29
Endnotes 30

**CHAPTER 3. COSTS OF TRANSPORTATION AND WHO PAYS: TRAVELLERS OR TAXPAYERS** 31

Introduction 31
Today's Subsidies and Costs — Hidden and Direct 32
System-Wide Costs 34
  Interpreting Table 3-1 and Chart 3-1 35
  Conclusions: Table 3-1 and Chart 3-1 43
Costs: Some Sample Routes 45
  Interpreting Tables 3-2 to 3-5 and Charts 3-2 to 3-5 45
  Conclusions: Tables 3-2 to 3-5 and Charts 3-2 to 3-5 55
Conclusion 57
Endnotes 58

**CHAPTER 4. NEW DIRECTIONS: FOUNDATIONS FOR A PASSENGER TRANSPORTATION FRAMEWORK** 59

Introduction 59
Foundations for a New Framework 59
  Objectives 60
  Principles for Travellers 65
  Principles for Carriers 68

Principles for Providers of Terminals, Links and Traffic Control 69
Implications for Governments 71
Functions of Government 71
Assigning Responsibility to Levels of Government 73
Equal Treatment of Modes 74
Accountability 74
Transition Mechanisms 75
Conclusion 77
Endnotes 78

## CHAPTER 5. TRANSPORTATION INFRASTRUCTURE: INVESTMENT AND PRICING 79

Introduction 79
Transportation Infrastructure: An Overview 80
Components of the Transportation System 80
Capital and Operating Costs 81
Making Investments in Transportation Infrastructure 82
Private-Sector Investment Decisions 82
Government Investment Decisions 82
The Principles of Infrastructure Pricing 83
Efficient Pricing 84
Marginal Cost 84
Pricing to Recover Total Costs 87
Pricing Networks 91
Applying the Principles to Terminals 93
Bus Terminals 93
Rail Stations and Ferry Terminals 94
Airports 94
Applying the Principles to Links 101
The Road Network 101
Air Links: Navigational Aids 106
Rail Links 108
Water Links 108
Applying the Principles to Control 109
Endnotes 110

**CHAPTER 6. MANAGING TRANSPORTATION INFRASTRUCTURE: THE INSTITUTIONS** 111

Introduction 111
Alternative Institutional Arrangements 112
  Private-Sector Providers of Transportation Infrastructure 113
  Public-Sector Providers of Transportation Infrastructure: The Options 116
  Public-Sector Providers of Transportation Infrastructure: Related Issues 119
Airports 121
  Local Airport Authorities (LAAs) 122
  The Impact of Federal Policies on Costs 124
  Guidelines for Airport Reform 125
Air Navigation 126
  The Role of the Federal Government 128
  An Independent Institution 128
Roads 129
  Transit New Zealand: A Model 129
  Guidelines for Provincial and Territorial Road Agencies 130
  The National Highway System Proposal 131
Control of Rail Tracks, Stations and Trains 136
  Ownership and Competition Issues 136
  Improving Access to Rail Tracks 137
  Rail Rationalization 143
Endnotes 148

**CHAPTER 7. PROTECTING THE ENVIRONMENT** 151

Introduction 151
How Transportation Contributes to Environmental Damage 152
  Low-Level Ozone Inducing Emissions 152
  Urban Sprawl 154
  Global Warming 154
Assessing Environmental Damage 156

Controlling Environmental Damage 157
  Coordination and Cooperation 159
  Protecting the Environment Through Regulation and Education 161
  Protecting the Environment Through Pricing 163
Comparison of Potential Emission Charges by Mode 166
Endnotes 173

**CHAPTER 8. IMPROVING SAFETY** 175

Introduction 175
Intercity Passenger Transportation Safety 175
  Airplane Safety 176
  Train Safety 179
  Bus Safety 180
  Ferry Safety 182
  Car Safety 182
Comparison of Safety by Mode 183
The Costs of Accidents 184
Who Pays for Accident Costs? 187
Who Pays for the Cost of Accident Prevention? 188
  Infrastructure Design and Services 188
  Regulation of Operators and Performance 189
Recommendations 189
Endnotes 192

**CHAPTER 9. EASING THE WAY: ACCESS TO TRANSPORTATION FOR PEOPLE WITH DISABILITIES** 195

Introduction 195
The Current Situation: Frustration and Progress 195
  The People Most Affected 195
  Expectations for Improvement in Access 198
  What Progress Has Been Made? 198
Recommendations 202
  Rights to Access 203
  Making Equipment and Infrastructure Accessible 203

Carrier Costs 205
Attendants and Identification Cards 206
Training of Transportation Personnel 208
Comfort 209
Intercity Buses 209
Coordination of Efforts 209
Endnotes 212

**CHAPTER 10. APPLYING THE PRINCIPLES TO CARRIERS: AN OVERVIEW** 215

Introduction 215
Private Carriers 215
Travel by Private Car 216
Travel by Private Airplane 218
Public Carriers 219
"Fit, Willing and Able" 220
Air Carriers 222
Rail Carriers 223
Intercity Bus Carriers 223
Ferries 224
Endnotes 225

**CHAPTER 11. APPLYING THE PRINCIPLES TO AIR CARRIERS** 227

Introduction 227
What Canadians Told Us 227
Government Policies of the Past 228
Current Government Policies 231
Changes under Economic Deregulation 232
Airline Performance under Economic Deregulation 236
Prices and Costs 236
Quality of Service 239
Market Structure and Competition 241
International Air Policy 246
Bilateral Air Agreements 246

Recommendations 248
    Ownership and Control 248
    Consolidation of the Industry 250
    Open Skies 253
Endnotes 256

## CHAPTER 12. APPLYING THE PRINCIPLES TO RAIL CARRIERS 259

Introduction 259
The Passenger Rail Industry in Canada 259
What Canadians Told Us 262
VIA Rail 263
    Financial Picture 263
    Services and Costs 264
    Comparing VIA Rail with Amtrak 268
    The Future of VIA Rail 274
    Recommendations for Passenger Rail 277
Remote Services 280
High-Speed Rail 281
Endnotes 285

## CHAPTER 13. APPLYING THE PRINCIPLES TO INTERCITY BUS CARRIERS 287

Introduction 287
The Bus Industry in Canada 287
    Markets 287
    Regulatory Environment 288
    Costs and Revenues 288
    Trends 289
What Canadians Told Us 290
    The Public 290
    The Industry 290
Government Policies: Past and Present 291
    Regulation 291
    Competition 293

The Effects of Regulation 293
    Cross Subsidies 293
    Other Effects 294
The Case for a Competitive Bus Industry 294
    The U.S. Experience 294
    The U.K. Experience 295
    Competition and Lower Fares 296
    Innovation 296
Competition Legislation and Enforcement 298
Service to Small Communities: The Transition 299
Endnotes 301

**CHAPTER 14. APPLYING THE PRINCIPLES TO FERRIES** 303

Introduction 303
What Canadians Told Us 305
Constitutional Obligations 306
    British Columbia 307
    Prince Edward Island and Newfoundland 308
Marine Atlantic and BC Ferries — Costs and Revenues 309
The Pricing of Ferry Services 311
Endnotes 317

**CHAPTER 15. INTEGRATING THE MODES** 319

Introduction 319
Integration Today 319
Airports — Most Integration Occurs Here 321
International Comparisons 325
Barriers to Integration 326
    The Car 326
    The Government's Role 326
    Competition 326
    Regulation 327
    Dismantling the Barriers 328

Recommendations: Moving Toward Integration 329
    Access to Terminals 329
    Anti-Competitive Practices 332
Endnotes 334

**CHAPTER 16. SEEING INTO THE SYSTEM: ACCOUNTABILITY AND TRANSPARENCY** 335

Introduction 335
What Canadians Told Us 335
    What They Want to Know 335
    Obstacles to Transparency 336
Accountability 336
    Benefits of New Institutions 336
    Recommendations for Accountability 337
The Need for More and Better Information 338
    What Canadians Need to Know 338
    Current Data Gaps 339
    Recommendations for Data Gathering 341
Transparency 341
Endnotes 343

**CHAPTER 17. IMPLICATIONS FOR INTERNATIONAL COMPETITION AND FOREIGN OWNERSHIP** 345

Introduction 345
Transportation Charges and International Competition 345
    Situations with No Competitive Disadvantages 346
    Situations Where Competitiveness is Affected 347
    Conclusion 350
Foreign Ownership 351
    Air Carriers 352
    Rail Carriers 353
    Bus Carriers 353
    Ferry Carriers 354

**CHAPTER 18. ADDING IT ALL UP: PASSENGER TRANSPORTATION COSTS — TODAY AND TOMORROW** 355

Introduction 355
Costs for Illustrative Routes 357
  Reading the Tables 358
  Route #1: Saskatoon to Halifax 360
  Route #2: Toronto to Montreal 367
  Route #3: Churchill to Winnipeg 371
  Route #4: Halifax to St. John's 375
Total System Costs 382
  Total Costs in the 2000 Status-Quo Case: Table 18-5 383
  Total Costs with Our Recommendations Implemented: Tables 18-6 and 18-7 385
Conclusion 393
Endnotes 394

**CHAPTER 19. REACHING OUR DESTINATION: A PASSENGER TRANSPORTATION FRAMEWORK FOR THE 21ST CENTURY** 397

Introduction 397
Achieving Our Framework 397
  Changes for Travellers 398
  Changes for Carriers 400
  Changes for Providers of Infrastructure 403
  Changes for Governments 406
  Transition Requirements 413
Meeting Our Objectives 416
  Improving Safety 417
  Greater Protection of the Environment 419
  Greater Fairness to Taxpayers, Travellers and Carriers 421
  A More-Efficient Transportation System 423
Reaching Our Destination 425

au Canada

*TO HIS EXCELLENCY*
*THE GOVERNOR GENERAL IN COUNCIL*

*MAY IT PLEASE YOUR EXCELLENCY*

*By Order in Council dated October 19, 1989 we were requested to inquire into and report upon a national integrated intercity passenger transportation system to meet the needs of Canada and Canadians in the 21st century and to ensure that transportation links among Canada's regions and communities are maintained and improved.*

*Having previously submitted an Interim Report in April 1991, we now beg to submit our Final Report in each official language.*

*Respectfully submitted,*

*Louis D. Hyndman, Q.C., Chair*

# FOREWORD — OUR VISION

In the autumn of 1989, nine Canadians came together to face a unique challenge. Our mission: to establish guideposts for the passenger transportation system that Canadian travellers will use well into the next century and to develop sensible recommendations for the system's future.

Strangers at first, we came to blend our widely different life experiences and to merge into this report what we heard and learned from Canadians. We knew that passenger transportation was not just wheels and wings, terminals and stations. Rather, our topic was people — Canadians who want to visit friends and relatives, do business or enjoy a holiday.

Looking at the road ahead, the Commissioners thought about the unlimited horizons of our young people who increasingly travel this remarkable country. We pondered the trend of increasing numbers of seniors who pride themselves on remaining active and considered people with disabilities who also want to move about easily in terminals, and on and off airplanes, trains, buses and ferries. We shared the worries of Canadian taxpayers who, like us, want more choice, less government, top value for their travel and tax dollars and a voice in the transportation decisions that affect them.

Above all, as the Commissioners travelled extensively throughout the country and met with Canadians from all regions and all walks of life, we were impressed by the vastness and diversity of the land we call Canada and, more importantly, by the people who call it home. We believe there is something called the Canadian culture, the Canadian soul, the Canadian way of life, the Canadian vision. This Canadian uniqueness is worth preserving, whatever the difficulties.

We realize that while the transportation system no longer plays the nation-building role it once did, it nevertheless remains an important element in linking Canadians to one another.

And what about tomorrow? The Royal Commission on National Passenger Transportation has a vision for the future of Canada's transportation system and the role it will play in our daily lives. The journey begins now. . . .

The year is 2012. Canada is a respected and fully participating member of the global community. Efficient, productive and competitive, Canada's resources, products and brain-power are in demand worldwide.

Canada is envied for its sense of fairness and respect for human rights. Potential immigrants continue to look upon Canada as one of the most favoured lands of opportunity. Canada continues to rank at or near the top of the list of "quality of life" countries in the world.

The Canadian passenger transportation system is a model for the world in this year 2012. Canadians travel across the land using a system that is even safer than it was back in 1992. Sophisticated navigation systems enable planes to fly in weather that would have shut down the system back then. Car accidents and deaths have been reduced by on-board radar systems, automated traffic control, stronger but lighter car bodies — even some automatically driven cars. In some parts of the country, special car, truck and bus lanes speed up traffic and reduce congestion.

Canada has achieved an enviable balance between sensitivity to environmental damage and the other objectives of the transportation system. Responding to public opinion and efficient pricing over the last 20 years, the transportation sector now builds much cleaner cars, buses, trains, airplanes and ferries.

Half the new cars sold are electrically powered, or are hybrids using propane or natural gas with gasoline. Travellers must pay more when they travel on the few remaining carriers that still have dirty engines. Pollution costs are printed on the tickets travellers purchase, and comparisons of the amount of damage caused by each mode of travel are given wide publicity.

There have been few expropriations of land for new rights-of-way or for airports in Canada since 1992, because existing highways and terminals are used more efficiently. Agricultural land no longer disappears under asphalt and concrete.

Canadians are applauded around the globe for the priority they assign to the interests of people with disabilities. Today, in 2012, there are millions more Canadians over 60 than 20 years ago. People working in passenger transportation place priority on assisting those who have walking, vision or hearing disabilities, and terminal designs and travel announcements are user-friendly to all.

New-technology trains that pay for themselves are planned for or are in operation between Vancouver and Abbotsford, Edmonton and Calgary, and Windsor and Quebec City.

A new kind of government leadership emerged during the 1990s. Governments removed themselves from virtually all aspects of transport operations to focus on their new role as policy makers, referees and standard-setters. The government transportation staff undertaking these tasks has been reduced from 120,000 in 1992 to 20,000 today. Canadians feel they have more local control over their passenger transportation system.

Canadians also have access to the facts about their passenger transportation system and know that they can move around the country in the most efficient way, without waste or duplication. Choices abound in fares, departure times and comfort levels. Taxpayers know that the system pays for itself, while travellers know and accept that they pay for all the costs they impose upon the system when they travel. Those who do not travel know that they no longer pay taxes to support those who do. Only a few small subsidies remain; most were phased out during the 1990s. In short, Canadians have the system they want, get what they pay for and pay for what they get.

The further opening of competition brought in more airlines, more bus companies of all sizes, more alternatives on rail tracks and more ways to move over water. Terminals which also double as local shopping malls, business offices, exhibition halls and community centres are shared by different carriers and modes, and provide convenient connections to other terminals.

Equally important, taxpayers are satisfied knowing that rigorous benefit-cost studies are mandatory for all transportation project proposals and that existing roads and airports are well maintained and operate at maximum efficiency.

That is our vision for the future. It is achievable. The recommendations that follow — when applied — will bring it about.

Louis D. Hyndman, Q.C.
Chair

Autumn 1992

# ACKNOWLEDGEMENTS

On presenting *Directions: The Final Report of the Royal Commission on National Passenger Transportation* to the Governor in Council of Canada, I am reminded of one of the more popular works by John Donne, in which he says: "No man is an island, entire of itself." I am, therefore, sincerely pleased for this opportunity to express my thanks to the many people who made this report possible. It is the work of many hands.

Firstly, I express my heartfelt appreciation and gratitude to my colleague Commissioners. When nine people from diverse professional and personal backgrounds are appointed to work on a common project, it is only through the utmost good faith and personal commitment that the endeavour can succeed. That diversity, good faith and personal commitment among my colleagues have made this a rewarding and rich experience for me. For their candor, their sound advice and their friendship as Canadians, I will be forever grateful. I know that they join with me now in expressing the following thanks.

The formidable challenge of assisting and supporting nine Commissioners, as well as the overall responsibility for the management of the Commission's work and inquiry operations, fell upon Dr. Janet R. Smith, the Commission's Executive Director. Her exceptional organizational and management skills kept the Commission operating smoothly at all times and gave us the freedom to devote ourselves exclusively to the inquiry at hand. We have all benefited from her extensive and incisive knowledge of the transportation sector and of government, her practical working experience and her penetrating intellect. Janet was, for me, a knowledgeable counsel and forthright confidante.

Many staff members joined the ranks of the Royal Commission on National Passenger Transportation during its three-year mandate, and we are indebted to all of them. They were frequently called upon to go that "extra kilometre," and they always delivered on time. Their names appear in Appendix B. Some among them call for special mention.

United in loyalty and support to our mission was a professional and highly proficient senior management complement: John Sargent, Director of Research; Helen Hardy, Deputy Director of Research; Brian Johnson, Director of Policy and Planning; Denise Ommanney, Director of Public Consultation; Linda Bergeron, Director of Communications; Nina-Maria Butcher, Director of Administrative Services; and Sherry Hudon, Executive Assistant to Dr. Smith and Secretary to Senior Management Committee.

The task of recommending a transportation framework for Canada in the 21st century required counsel and advice from the leading researchers in several specialized fields, and we were fortunate to find the highest calibre of expertise in our consultants. Our sincere gratitude goes to all of those who contributed to the research program of our final report.

Since transportation systems are closely associated to countries, our mandate required us to consult with our international transportation counterparts. We needed to observe first-hand the roles that their passenger transportation systems are playing and to evaluate how the solutions advanced by other countries to concerns similar to our own might apply to the Canadian experience. These international consultations expanded and enriched the context of our final report, and we would like to express to all whom we consulted our appreciation for their willing and frank exchange of information. We also want to thank Transport Canada and External Affairs and International Trade Canada for their helpful assistance in organizing these international exchanges.

Still on the consultation front, we wish to voice our deepest gratitude to all those Canadians who came forward during the public hearings and throughout our mandate to communicate their opinions and concerns about Canada's passenger transportation system. We heard from people with disabilities, business, labour, governments, seniors, young people and interested citizens. Commissioners were moved by the personal accounts of so many individuals who spoke and wrote to us about their experiences with the present transportation system. We were also impressed with the hope that Canadians have for a better system in the future. The best testimonial that we, as a Royal Commission, can offer these Canadians is to show them that we heard and listened to what they had to say: they will find many of their views and concerns addressed throughout the pages of this report.

The production of a comprehensive four-volume final report, especially one that deals with highly technical data, demands the finest quality of writing, revision, editing and translation. Commission staff, assisted by a team of professionals, strived to maintain not only a high quality of language and to keep the text readable for all Canadians. We thank Nadja Corkum and Claire Harrison of Astroff Corkum Ross Associates Inc. for their writing and editorial assistance with the English text, and Volker Junginger and Christine O'Meara of Tradunion Inc. for their translation and revision of the French version.

I would also like to express a personal note of thanks to Estelle Lord, my Administrative Assistant in Edmonton, for her loyal dedication and competent service.

And, finally, we acknowledge the patience of our families, who have endured our many absences from home during the work of this Royal Commission. Because of their support and understanding, we ask that they share in our pride and accomplishment.

Louis D. Hyndman, Q.C.
Chair

Autumn 1992

# CHAPTER 1

# POINT OF DEPARTURE

## SETTING THE STAGE

In October 1989, the Government of Canada asked us to "inquire into and report upon a national integrated intercity passenger transportation system to meet the needs of Canada and Canadians in the 21st century."[1]

### CHANGES IN THE WORLD COMMUNITY

During the three years of our mandate, we have witnessed unexpected and often dramatic changes in Canada and other countries. When we began our task in 1989, the great changes that have since swept Central and Eastern Europe and the subsequent redrawing of the political map had yet to occur. In Canada, the Meech Lake Accord appeared to be on its way to ratification. The Free Trade Agreement with the United States had been approved months earlier, and the North American economies were strong and growing.

Today, the U.S.S.R. is gone, and its successor states and the countries of Eastern Europe are struggling toward market economies. The General Agreement on Tariffs and Trade (GATT) is being challenged by the failure of its members to deal with the increasing competitiveness of modern economies in a wide array of sectors, from agriculture to intellectual property to services in general. The North American economies are battling a lengthy recession compounded by major economic restructuring. At the time of writing, Canadians are assessing, in a fundamental way, the nature of their country — by redefining national institutions and rethinking their approach to federalism.

Transportation around the world is also undergoing major change. Rail traffic in Eastern Europe has decreased as car sales have increased. The world's airlines have been hurt by recession and the 1991 Gulf War — many failed, others merged or were sold. Growing environmental problems are prompting increased public awareness of the need for global action in transportation and other sectors. The benefits of loosening government controls over the delivery of services are resulting in new approaches to meeting travellers' needs. Many countries are trying new ways to finance transportation infrastructure privately and to privatize government transportation services. We believe that this rapid pace of change will continue. Canadians cannot ignore these changes in other parts of the world, and the challenges that they present.

## WHY IT IS IMPORTANT TO MAKE THE RIGHT PASSENGER TRANSPORTATION DECISIONS

In total, Canadians in 1989 devoted substantially more resources to transportation than they did to health care — equivalent to 16 percent of gross domestic product (GDP) compared with 9 percent of GDP, respectively. Resources used to provide intercity passenger transportation accounted for 30 percent to 40 percent of total resources devoted to transportation, or 5 percent to 7 percent of GDP (depending on how extensively "intercity" travel is defined, particularly travel by private car).[2] This is an annual expenditure of $30 billion to $45 billion or $1,100 to $1,700 per Canadian. As the economies of nations become more and more interdependent, the choices that Canadians make about passenger transportation projects and investment will affect Canada's economic success in the global marketplace.

Revolutions in communications technology are changing the way businesses operate and are encouraging globalization of markets.[3] For example, the production, marketing and financial systems of large multinational corporations are increasingly integrated on a global basis. In the future, the quality of life in all countries will depend on their ability to adjust to a world in which there are fewer national barriers to the movement of capital, labour, goods and services.

Many sectors of the Canadian economy, such as the tourism industry and manufacturers who sell goods and services abroad, depend on the transportation system to provide cost-effective service so that they, in turn, can better serve their customers. Passenger transportation companies must look for ways to improve services and lower prices.

### PUBLIC CONCERNS OVER PASSENGER TRANSPORTATION

On most trips taken, no matter by which mode, the taxpayer is often an unwitting partner. Travellers want more and improved passenger transportation services, but taxpayers are increasingly reluctant to bear the consequent financial burden. Some Canadians travel frequently and use the passenger transportation system extensively. Others travel seldom, or not at all, yet their taxes help pay for those who do travel. Even if current budgetary pressures abate, the public will continue to pressure the government to spend wisely — by maintaining the passenger transportation system when funds are limited and not over-building it when funds are plentiful.

Concerns about how transportation affects the environment have moved to the fore. Transportation leads to traffic congestion, causes air and noise pollution, and consumes land for roads, airports and parking lots. As Canadians become more aware of the impact of transportation on human health and the long-term well-being of the planet, environmental issues are becoming a more important factor in passenger transportation decisions. Governments at all levels face growing public pressure to regulate the transportation sector for greater protection of the environment.

## OUR ACTIVITIES

In the course of our three-year mandate we consulted with Canadians, studied passenger transportation in other countries and undertook a research program.

## CONSULTING WITH CANADIANS

Through public hearings, written submissions, toll-free telephone lines and consultations, we listened to Canadians who have an interest in passenger transportation. These included travellers and providers of transportation infrastructure and services, as well as governments, taxpayers, unions and regulators.[4] We wanted to understand the needs and aspirations of travellers, to ascertain the concerns of those who provide passenger transportation infrastructure and services, and to identify the issues and problems.

## STUDYING PASSENGER TRANSPORTATION IN OTHER COUNTRIES

We also looked at how other countries are dealing with passenger transportation issues. Rapid political and economic change is affecting many nations, and we discovered that Canada is not alone in questioning the traditional ways of making passenger transportation policy and investment decisions, nor in seeking new ways to resolve transportation issues. Governments around the world are exploring ways to improve the efficiency of their transportation systems.

Several countries have recently undertaken major transportation studies, and some are already putting recommendations into practice. The United States, Switzerland, Sweden, and The Netherlands are approaching transportation issues from a broad perspective. They have developed, and are beginning to implement, long-term strategies that deal comprehensively with the issues in all transportation modes.[5] Other countries have undertaken studies that focus on specific problems and modes. Australia and Germany have examined escalating deficits and other issues in the rail sector.[6] Australia has been studying, and changing, road user-charges and air transportation regulation. New Zealand has made major changes in the way it provides roads and charges road users.

Many countries have relaxed government controls and economic regulation over their passenger transportation carriers. The United States, Australia, New Zealand and the United Kingdom view transportation less as an instrument of public policy and more as an economic activity that can benefit from the tests, economic discipline, creativity and incentives of the market. Many countries are studying ways of setting prices that reflect the costs of transportation services and infrastructure:

- In the United States, a government report is explicit about the need to "assure that transportation users bear the maximum practical and appropriate share of the costs of services and facilities they use."[7]
- In Sweden, legislation emphasizes that transportation prices to travellers must include the costs of pollution, congestion and traffic accidents.[8]
- In Norway, an extensive toll system exists around Oslo city centre, and drivers using downtown streets must pay a charge that is intended to discourage city driving.
- In Singapore, city traffic is controlled through an area licensing scheme. Authorities auction limited numbers of special licences that all vehicles must have when entering and operating within the restricted zone.

Several countries are experimenting with alternative transportation ownership and administrative arrangements:

- In 1986, the Australian government transferred the responsibility for planning and operating the country's major airports to a Federal Airport Corporation.
- New Zealand established Transit New Zealand — a quasi-autonomous authority — to manage its roads, and the revenues from road-user charges were earmarked to cover the expenditures of the road authority.
- In 1987, the United Kingdom privatized its main airports, transforming the government-owned British Airports Authority into a private-sector company.

- In France, Italy and Spain, extensive systems of toll highways operate under private or mixed private-public ownership.
- Germany and the United Kingdom have announced plans to privatize their government-owned railway companies.
- A number of other countries are inviting private firms to participate in the development, financing, construction, maintenance and operation of roads, bridges and tunnels, such as the Channel Tunnel between the United Kingdom and France.

## RESEARCHING INTERCITY PASSENGER TRANSPORTATION IN CANADA

Through our research program, we examined many aspects of intercity passenger transportation: how and where Canadians travel, the costs and who pays them, the safety of each mode, and the extent to which transportation affects the environment. We continued throughout our mandate to consult with travellers, providers of passenger transportation infrastructure and services, government officials and experts in Canada and abroad. We used our research and consultations to sharpen our understanding of the issues.

We concluded that the way the transportation system in Canada is managed is no longer adequate, for the following reasons:

- Governments often make passenger transportation decisions based on conflicting objectives.
- Although some travellers pay fully for their transportation, most travellers do not, and in no mode of travel are costs fully covered by fares, licences and fees paid by those who use the mode.
- Individual carriers face different rules and regulations. For some carriers, competition is the driving force; others operate as monopolies.
- Prices rarely reflect the costs of a traveller's use of the transportation system. As a result, travellers from well-used parts of the system help pay for parts that are used less often.

- Passenger transportation costs are sometimes higher than necessary because governments have not always invested in projects that yielded the highest positive return.
- Governments, industry and travellers rarely give full weight to the environmental and other social costs of transportation.
- Taxpayers do not have enough information about why particular decisions are made, or how their tax dollars are spent.

## OUR APPROACH

We have taken a long-range, comprehensive view of the passenger transportation system. Our program of study, consultation and research gave us a unique opportunity to step back from current day-to-day issues and view the passenger transportation system through a wider lens than that used by those who must deal daily with transportation problems. We want to help resolve not only today's issues and problems, but those of tomorrow as well.

### OUR METHOD

From the start, we wrestled with two ways of accomplishing our task. One method was to address, individually, the hundreds of problems facing today's passenger transportation system. We could have approached our task by listing the current passenger transportation issues, attempting to resolve them, and then looking for consistency and coherence in our solutions.[9] But we believe this method alone would fail, because such solutions would not be based on a long-term goal nor on clear objectives. The result would likely be passenger transportation recommendations that were inconsistent, short-term and wasteful.

The second method was to develop a long-term passenger transportation framework. We believe that the framework (the laws, regulations and institutions that govern transportation) must be developed by setting a goal and developing objectives that Canadians agree upon.

With a guiding framework in place, future passenger transportation decisions will be coherent, consistent and less expensive after all costs paid by all parties are taken into account.

## OUR DIRECTIONS

The directions that we recommend in this report, when followed, will not just mirror but will be in the forefront of the evolution of passenger transportation policy worldwide. Our recommendations will result in:

- a passenger transportation system that is safe;
- a passenger transportation system that protects the environment;
- a fairer passenger transportation system in which the costs would be paid by the people who benefit;
- a less expensive system where all costs are taken into account, with services better matched to traveller demand; and
- lower general taxes, resulting from lower total costs and the transfer of costs from the taxpayer to the traveller.

## OUR GUIDING PHILOSOPHY

We looked at two possible underpinnings for a passenger transportation framework — a subsidized transportation system and a traveller-funded transportation system.

Subsidized transportation results in lower prices for the traveller but higher taxes for citizens, whether they travel or not. We considered this option carefully, because it is similar to those used by governments in the past. For example, building the Canadian Pacific Railway (CPR) in the 1880s and developing the airline industry in the 1940s involved taxpayer expenditure. Today, however, transportation systems are reasonably well developed, and governments and industry must spend more on maintenance of the existing system than on new infrastructure. What was appropriate for a system in the process of development is not appropriate for one that is mature.

Some Canadians who spoke with us argued that a transportation system massively supported by the general taxpayer would make Canada more competitive internationally by lowering the costs of transportation as part of doing business. We found, however, that heavily subsidized transportation in other countries resulted in skewed business investments and activities, and inefficient, uncompetitive economies. For example, transportation in Eastern Europe and South America was, until recently, heavily subsidized, with no real improvement in prosperity and productivity. Even countries in the European Community are now assessing the results of large subsidies to their rail systems.

We believe that, unless our transportation system is made efficient now, Canadians will pay dearly later for the adjustments needed to survive in the global marketplace. We have chosen to build a framework on the basic philosophy that transportation should be provided through a system supported and maintained by its users and not through government departments and central controls. We see the transportation sector as requiring a different approach from such government-supported and controlled sectors as health and education, and relate it more closely to providers of services such as telecommunications and electric power. Transportation would lose its tax-supported base and transportation infrastructure and services would be provided according to the willingness of travellers to pay for them.

## THE PAST AND THE FUTURE

The passenger transportation policies of the future would not mirror those of the past. In particular:

- In the past, government has regulated the economic aspects of passenger transportation systems and has provided much of the infrastructure. We believe these systems should be open and accessible, and that government should confine its role to being a referee and policy setter.
- In the past, jurisdiction over passenger transportation has often been divided in an inconsistent and contradictory way among levels of government. We believe that responsibilities should be assigned to the lowest level of government that can efficiently handle them, be that municipal, regional, territorial, provincial or federal, or a combination of these.
- In the past, the passenger transportation system has depended on funding from taxpayers whether they travel a little, a lot, or not at all. We believe that the passenger transportation system is now sufficiently mature to be self-sustaining, so that travellers should pay for what they get and get what they pay for.
- In the past, governments have made passenger transportation decisions without sufficient accountability to those who pay taxes or user fees. We believe that passenger transportation decisions should be visible and understandable and that all costs should be made public. The transportation system should be transparent in its accounts and accountable in its decision making.

We recognize that moving the transportation system out of government control right away would have major implications for industry and travellers. We therefore suggest transition periods to allow the passenger transportation system to adjust to being more autonomous, more accountable, more economically viable and more protective of the environment. These transition periods should be short and must not be an excuse for inaction or delay in the implementation of our recommendations.

## MOVING FORWARD

In the chapters that follow, we develop a passenger transportation framework for the future and make recommendations that implement it. We have organized this Report as follows:

- Chapter 2 presents a view of the Canadian passenger transportation system — past, present and future.
- Chapter 3 looks at the costs of the current passenger transportation system and who pays the costs.
- Chapter 4 discusses the principles underlying our framework. We make recommendations on a goal and on objectives for the passenger transportation system. We discuss the implications for governments, travellers, taxpayers, carriers, and providers of infrastructure. We also address transition mechanisms.
- Chapters 5 to 15 apply our principles to the existing passenger transportation system, addressing environmental, safety and accessibility issues, and analyzing the implications of our principles for each of the different modes.
- Chapters 16 and 17 address special transportation concerns — accountability, transparency and international issues.
- Chapter 18 examines changes in who will benefit from the new framework and who will pay.
- Chapter 19 summarizes the changes in legislation, regulations and institutions necessary to implement the framework and describes how these changes will meet our objectives.

We sought — and believe we found — Canadian solutions to Canadian problems. These proposals will lead to a significantly improved passenger transportation system that will encourage competition, creativity and technological change, will give most Canadian travellers the widest array of choices, and will ensure that non-travelling Canadians do not have to pay the bill for those who do.

# ENDNOTES

1. See Appendix A, Volume 1 for full Terms of Reference.

2. These figures correspond to comprehensive measures of the resources used to provide transportation, health, and intercity passenger transportation. In the case of transportation, they include both services used directly by consumers and governments, and services that are used by businesses to produce non-transportation goods and services. Our measure covers transportation services provided by commercial carriers (indicated by their revenues), and transportation "produced directly" by the user. Private purchases of cars and car operating expenses are used as an indicator of the personal component of direct production. The costs of government-provided transportation infrastructure (not already reflected in charges to travellers included in carrier revenues) are included in the operating costs of those providing their own transportation services.

   The low end of the estimated range of resources devoted to intercity travel defines "intercity" trips as trips longer than 80 kilometres in one-way distance. The high end of the range defines intercity trips as all trips by air, rail (excluding urban transit), intercity bus, ferry (apart from urban and short river crossing ferries) and all car travel on provincial highways. When comparing the roles of the different means of transportation, especially in chapters 2 and 10, we are guided by the narrower definition. In chapters 3 and 18, where an important element is the costs of different types of infrastructure, we use the wider definition.

   A different approach to measuring the "size of the transportation sector" is to include only the value added of transportation carrier industries, which is, for all transportation (freight and passenger, urban and intercity), about 4 percent of GDP. By comparison, the value added in the health care services, hospital and pharmaceutical industries is 7 percent of GDP.

   For a more complete discussion, see Notes to Chapter 1 and Notes to Chapter 2 in Volume 2 of this report.

3. Over the past two decades, the volume of world merchandise trade has been growing more rapidly than that of world output. And, during the 1980s, world outflow of foreign direct investment grew much more rapidly than world merchandise trade. Source: Economic Council of Canada, *Pulling Together: Productivity, Innovation and Trade* (Ottawa: Supply and Services Canada, 1992).

4. For a full discussion of what Canadians told us, see Chapter V of *Getting There: The Interim Report of the Royal Commission on National Passenger Transportation* (Ottawa: Supply and Services Canada, 1991).

5. The Swiss government created the 62-member Federal Commission for a Swiss Integral Concept of Transport in 1972, whose report — *Rapport Final sur les travaux de la Commission féderale de la conception globale Suisse des transport* — was published in 1977. Sweden published its *Transport Policy for the 90s* in 1988. The United States released its major transportation review, *Moving America*, in 1990. The Netherlands developed its *Second Transport Structure Plan* in 1990.

6. The report of Australia's Industry Commission, entitled *Rail Transport*, was released in October 1991, roughly at the same time as that of the Government Commission on German Railways.

7. The U.S. policy statement is found in *Moving America*, p. 56.

8. *The Transportation Act, 1979* and *Transportation Act, 1988*.

9. See *Getting There: The Interim Report of the Royal Commission on National Passenger Transportation*, pp. 159-162 (Ottawa: Supply and Services Canada, 1991).

# CHAPTER 2

# CANADIAN PERSPECTIVES: PAST, PRESENT AND FUTURE

## INTRODUCTION

Our inquiry is timely. The world is changing and Canada is changing with it. These changes present opportunities and challenges to those who will be making transportation decisions today and for the future. We firmly believe that our recommendations will help them choose well.

How can Canada take advantage of these opportunities and meet the challenges? Some guidance is found by examining the historical forces that shaped Canada's passenger transportation system, and by studying the current trends that will affect the transportation system in the future. Therefore, in this chapter, we examine the past, describe the passenger transportation system of today, and explore the possibilities for the passenger transportation system of tomorrow.

## AN HISTORICAL PERSPECTIVE

Early colonists used lakes and rivers as natural highways into the interior of the country. In the 18th century, the earliest forms of water transportation, such as canoes, were supplemented for commercial purposes with schooners and flat-bottomed boats. Early in the 19th century, the introduction of the steamship brought formalized, mostly privately owned, marine passenger transportation with regular schedules, set fares and different classes of accommodation.

From the 19th century to the middle of the 20th century, governments and industry built the transportation infrastructure that was needed to support Canada's developing economy. As new forms of transportation were introduced, new types of infrastructure were developed:

- In the 19th century, the Welland, Lachine and Rideau canals were constructed, and thousands of miles of railway track were laid.
- By 1885, the first transcontinental railway was completed. The laying of railway tracks continued at a rapid pace into the second decade of the 20th century.
- In the 1920s, the popularity of the car spurred the development of roads. Road building continued for several decades, including the construction of the Trans-Canada Highway from 1949 to 1965.
- Also in the 1920s, commercial air services were introduced. In the 1950s, their growth led to the development of new airports, and the modernization of air navigation and air traffic control systems.

## PAST ROLES OF GOVERNMENT

Early in Canada's history, governments considered the building of canals and laying of railway tracks to be private-sector enterprises. Many large-scale projects, however, turned out to be expensive and not commercially viable. Gradually, governments became involved in the financing, ownership and management of transportation infrastructure and services. Governments often stepped in with financial assistance in the form of subsidies, loans and loan guarantees to make the projects viable for private-sector investors.

Public support assisted the Canadian Pacific Railway Company (CP) in constructing the transcontinental railway. To attract a private syndicate to undertake construction, the federal government offered land grants of 25 million acres (10 million hectares), a cash subsidy of $25 million (equivalent in today's dollars to 15 to 20 times this much or $350 million to $500 million), and a series of privileges (including the promise of a 20-year monopoly on traffic in the area between the main line and the U.S. border). With government support, a successful railway company developed that still operates today.

Despite government financial assistance, the private sector often failed. Government had to assume ownership of the privately owned Welland and Lachine canals to keep these services operating. Also, many private railway companies overextended themselves. In 1919, the federal government consolidated many of these railways under the control of the Canadian National Railway Company (CN).

Provincial governments began to invest in road development in the 1920s, and road building continued through make-work projects during the Depression of the 1930s. Following World War II, a surge in car sales and the growth in truck transportation led to pressures for more road paving and modernization. During this period, road construction and maintenance became a major area of spending by provincial governments.

Federal government involvement in transportation increased during World War II as the development of air services was added to the earlier roles in marine and rail services. After the war, the federal government played a major role in the financing of air infrastructure by building airports, expanding the air navigation system and assuming ownership of many airports. Between 1951 and 1961, federal capital spending on air services increased nearly ninefold. The federal and provincial governments also participated jointly, for the first and only time in a major transportation project, in the construction of the Trans-Canada Highway.

Governments also controlled passenger transportation carriers. Throughout this period of expansion, federal regulations governed air and rail carriers and provincial or territorial regulations governed car, truck and bus operators. These regulations controlled almost every economic aspect of passenger transportation, including starting a business in the industry, choosing routes, setting fares and establishing standards for service.

By regulating the industry, by owning carriers (such as CN and its subsidiary, Trans-Canada Airlines, established in 1937) or by combining ownership and regulation, governments used transportation services to further various public policy objectives. They believed that the profits generated in some passenger transportation markets should subsidize other, unprofitable markets.

## CHANGING ROLES OF GOVERNMENT

By the early 1960s, governments began to study the effects of early transportation policies. During the 19th and early 20th centuries, the focus was on developing and building Canada's transportation system. By 1960, governments began to examine the transportation system in a different way. Although there were still areas where they felt new government investment was required to expand and upgrade infrastructure, the main modes and routes of transportation were now well established and the passenger transportation system had matured.

In 1961, the MacPherson Royal Commission on Transportation reported on the freight railway transportation system. It criticized government policies that hampered the railways' abilities to compete with other modes in the transportation of freight. Although the MacPherson Royal Commission's range of study was narrow, its conclusions had implications for transportation well beyond that of the freight railway system. Its findings influenced the 1967 *National Transportation Act* (NTA), the first federal transportation law that encompassed all modes of transportation. The new Act emphasized the need for competition between the air, rail, truck and bus modes to help achieve an "economic, efficient and adequate transport system."[1]

While the 1967 NTA promoted competition among modes, it did not eliminate economic regulatory restrictions on competition within modes. Air and water carriers, along with rail, truck and bus operators, were still subject to strict economic regulation.

In the 1970s and early 1980s, governments came under increasing pressure to relax many of these economic controls. The United States substantially reduced economic regulation in its transportation sector, and Canadian travellers and shippers pushed for reforms that would provide them with the same low costs as those experienced by users of the transportation system in the United States.

In response, the Government of Canada introduced a number of reforms in the late 1970s and early 1980s, and enacted the *National Transportation Act, 1987* (NTA, 1987). This Act declared that "a safe, economic, efficient and adequate" system is most likely to be achieved when "all carriers are able to compete both within and among the various modes of transportation." The major impact of this legislation on passenger services was on one mode only; it virtually eliminated entry, exit and price controls on the domestic airline industry. In addition, the federal government privatized Air Canada in 1988 and 1989.

The federal government also enacted the *Motor Vehicle Transport Act, 1987*, which resulted in a gradual dismantling of provincial regulatory controls over the trucking industry. Provincial governments continue to regulate intercity passenger buses, although New Brunswick and Prince Edward Island have recently eased entry requirements, and Alberta has opened entry to charter bus operations to anyone who can meet a minimal "fit, willing and able" test.

Many of the recommendations of the 1961 MacPherson Royal Commission, which emphasized the need for governments to repeal regulations and allow more competition in transportation, were implemented over 30 years.

## CANADA'S PASSENGER TRANSPORTATION SYSTEM TODAY

Intercity passenger transportation today is big business. We estimate that, in 1989, spending on intercity passenger transportation by Canadian travellers and taxpayers was in the $30 billion to $45 billion range, (depending on how extensively "intercity" is defined, especially as regards travel by car[2]). This figure includes passenger services on intercity carriers, the intercity portion of car use including car purchase costs, and the portion of government spending on the infrastructure component of the system.

Intercity passenger transportation provides employment to many Canadians. In 1991, intercity passenger carriers employed some 70,000 people and many more Canadians worked on related aspects of the transportation system. For example, they constructed and maintained roads, airports, and the air navigation system; they built and serviced cars, trucks and buses; and they produced and sold the oil, gas and parts used by the transportation sector. Governments, at all levels, are major employers in the system, as owners and providers of transportation infrastructure and services. They also employ smaller numbers of people in regulatory and policy functions. For example, Transport Canada employs approximately 21,000 people, and all governments — federal, provincial, territorial and municipal — employ approximately 100,000 in transportation and communications.[3]

Intercity passenger transportation is a complex system of interrelated components. Passenger transportation consists of the road, air, rail, and water modes of travel. It can be divided into two components:

- carriers that provide bus, airplane, train and ferry services together with privately owned passenger vehicles — cars, light trucks and vans (for ease in this report we refer to these vehicles as cars); and
- infrastructure that consists of the terminals where carriers start and stop, the "links" over which carriers operate, and the traffic control systems that direct the behaviour of carriers.

Table 2-1 illustrates the components of the transportation system.

The intercity passenger transportation system is connected to urban transportation systems and there is no clear boundary between traffic that occurs between cities and that which takes place within cities. It is also often the same system that carries freight.

*Table 2-1*
*COMPONENTS OF THE TRANSPORTATION SYSTEM*

| | | **Infrastructure** | | |
|---|---|---|---|---|
| **Mode** | **Carrier** | **Terminals** | **Links** | **Traffic control** |
| **Road** | Cars | Car parking | Roads (including bridges) | Police, road signs and signals, traffic control laws and regulations |
| | Buses | Bus terminals | | |
| **Air** | Airplanes | Airports (including runways) | Air navigation systems | Air traffic control |
| **Rail** | Trains | Stations | Railway tracks | Dispatch, signal systems |
| **Water** | Ferries | Ferry terminals (including wharves and ferry slips) | Waterways and canals (including navigational aids) | Vessel traffic services |

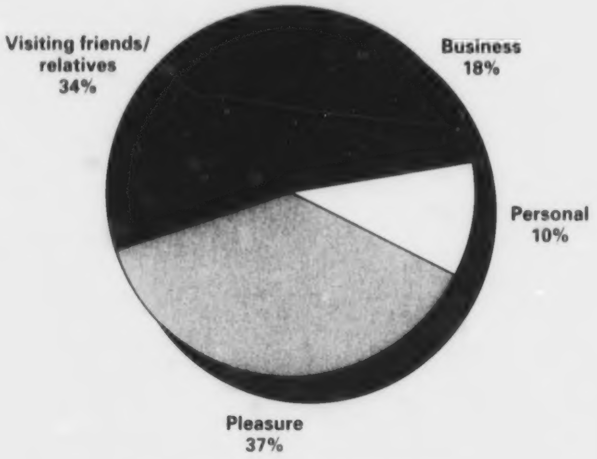
## WHY CANADIANS TRAVEL

Intercity passenger transportation is an important part of Canadian life. Passenger transportation enables Canadians to pursue private and business goals. It connects region to region and city to city, providing people with the opportunity to meet for business, visit friends and family, or expand their horizons. In 1990, Canadians took over 150 million intercity trips, of which 134 million were within Canada, an average of five trips per Canadian.[4]

Most Canadians who travel do so for vacations, sightseeing and to visit friends and relatives. Business travel accounts for a small share of intercity travel within Canada (Chart 2-1).

Most intercity trips in Canada are over short and medium distances and occur within, rather than between, provinces or territories. In 1990, 76 percent of trips taken were between 80 and 320 kilometres one way (Charts 2-2 and 2-3). However, one-way trips over 320 kilometres account for over 60 percent of passenger-kilometres travelled.

*Chart 2-1*
*DOMESTIC INTERCITY TRAVEL BY MAIN PURPOSE OF TRIP, 1990*



**Total: 133.8 million person-trips**

**Source:** Statistics Canada, *Touriscope: Domestic Travel 1990*, Catalogue No. 87-504, October 1991, p. 27.

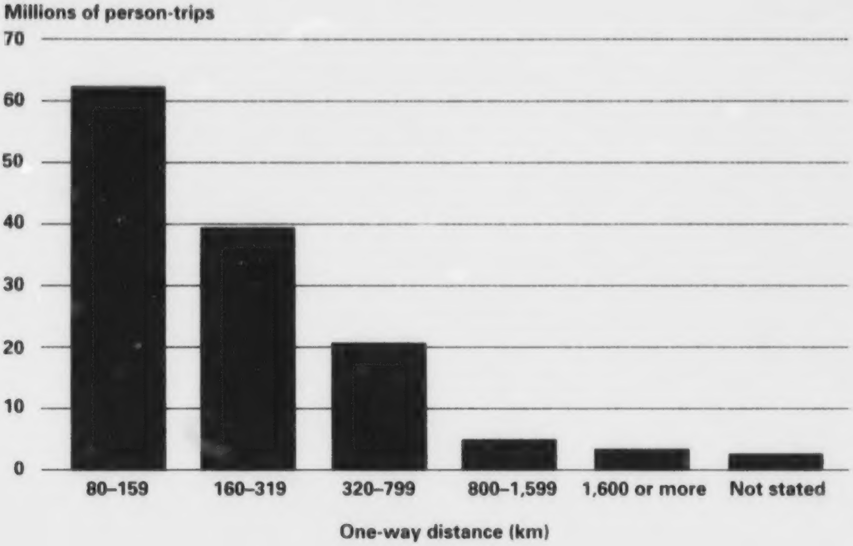
**Note:** Total person-trips include a "not-stated" category.

## HOW CANADIANS TRAVEL

The car is the favourite mode of intercity travel for Canadians, as well as for citizens of all the other developed Western countries. In 1990, around 80 percent of all domestic intercity[5] passenger-kilometres travelled in Canada were by car. Although the car is used for only a small proportion of trips over 3,200 kilometres, it is the most popular means of travel in all other distance categories (Chart 2-3).

For Canadians, the car is also the most popular means of international travel (mostly to the United States), although 35 percent of all international trips are by air (Chart 2-4). International car travel is popular because the United States is, by far, the chosen destination

*Chart 2-2*
*DOMESTIC INTERCITY TRAVEL BY DISTANCE OF TRIP (ONE-WAY), 1990*



**Source: Statistics Canada, *Touriscope: Domestic Travel 1990*, Catalogue No. 87-504, October 1991, p. 27.**

of Canadians travelling outside the country. In 1990, 85 percent of all international trips taken by Canadians were to the United States. As with domestic travel, most international travel by Canadians is for vacations and to visit friends and relatives, rather than for business.

In terms of ways to travel, Canadians' choices have remained rather stable over time. As Chart 2-5 shows, the car has been the dominant mode of passenger transportation since 1930, except during World War II. Airplane travel has grown in importance since its beginning in the 1930s, and has become the dominant public mode of travel. The relative importance of bus and train travel has declined over the last 50 years.

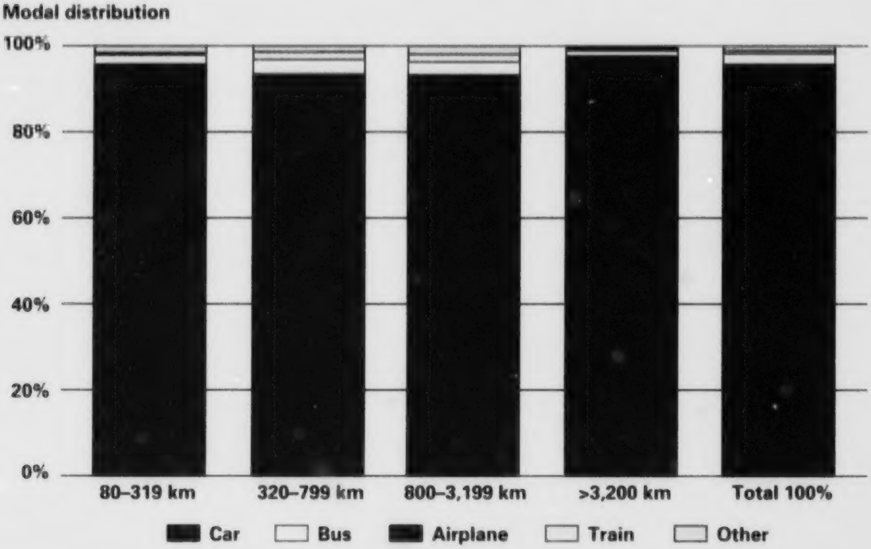
***DOMESTIC INTERCITY TRAVEL BY MODE AND TRIP LENGTH, 1990***



**Source:** Unpublished data from Statistics Canada's Canadian Travel Survey.

**Note:** "Other" category includes boat, motorcycle, bicycle, and means not specified by survey respondent.

Canadian travel patterns differ from those of some countries but not in the strong attachment Canadians have for cars. As shown by the international comparative data in Chart 2-6 and Table 2-2, the car is now almost as important a mode of transportation in the United Kingdom and (the former West) Germany as it has been in Canada and the United States for decades. In France and Italy, the car is also the dominant mode. In all these countries, car use has increased

appreciably over the past quarter of a century. In Japan, car use is also growing, although train travel continues to be more important than in Canada and the United States. Train travel also continues to play a somewhat larger role in Western Europe. Most countries, however, are experiencing the same long-term decrease in the importance of the bus and train travel that has been observed in Canada. Airplane travel, by contrast, has increased its share of passenger travel everywhere — most markedly in the United States. The increased importance of airplane travel would be even more apparent for a number of other countries if international travel were included in the data.

**Source:** Royal Commission staff calculations based on data from Statistics Canada the European Conference of Ministers of Transport, and a number of U.S. and Japanese sources. For details consult the Notes to Chapter 2 in Volume 2 of this report.

**Notes:** This table covers total domestic, not just domestic intercity, passenger transportion.

Data on total travel were used since internationally comparable data on the intercity portion of travel are not available. If intercity data were available, they would logically show an increased share for air, a decreased share for bus, and possibly a somewhat increased share for rail and somewhat decreased share for car.

Data may not be fully comparable across countries; thus the table should be used to make broad comparisons and significance should not be attached to small differences.

For geographically compact countries, domestic air travel may be unimportant. Data on total domestic and international air travel could be expected to show a much larger share for air for these countries.

** indicates share of less than 0.5%.

## CANADA'S PASSENGER TRANSPORTATION SYSTEM: 1992 AND BEYOND

How much and what kind of transportation will travellers want, and be willing to pay for, in the next 30 years? What kinds of transportation services will be available? There is always a great deal of uncertainty when looking into the future. Passenger transportation requirements are the result of many factors — for example, the country's economic performance and the income levels of Canadians, changes in work patterns and lifestyles, and the development of new technology.

Extrapolating on present directions in passenger transportation provides some indication of future directions. Based on current trends:

- The car will remain the preferred mode of transportation and will dominate the public modes.
- In recent years — the only years for which we have data — people aged 25 to 54 have tended to travel more than those in younger and older age groups. As Baby Boomers have moved into adulthood and middle age, travel has increased. Over the next decade, changes in the age structure of the population will have relatively little impact on the total amount of travel. But after the turn of the century, the movement of the Baby Boomers into older age

groups will, if current travel patterns persist, tend to slow the growth of travel.

- Most long-distance travel, including almost all travel in the North, will continue to be by air.
- As a result of its small population and market, Canada will mainly rely upon transportation technology developed elsewhere. Canadian governments can set Canadian requirements for airplane emissions, but if companies based in other countries do not build equipment to those specifications, Canada will be limited in what it can do to influence the introduction of new technologies.
- Canada shares an international border with the United States, a country whose economy is ten times as large. Canada will have to continue taking account of its physical link to the United States in making future passenger transportation decisions.
- Canada's climate will continue to affect the costs of transportation. A cold climate makes transportation more expensive for several reasons: it affects the design, construction and life-cycle of vehicles and infrastructure; the costs of operations; and the seasonal demands for some infrastructure and equipment.

Projecting current trends, however, may not paint a complete picture of future transportation requirements, for a number of reasons:

- The demand for travel in the future, within each age group, could be different from today's pattern. For example, advances in medicine, changing lifestyles, and rising per capita income could mean seniors of the future will travel more than seniors do today.
- An aging population, which would have more leisure time and a higher proportion of citizens with disabilities, could have different preferences in choosing modes of transportation.
- Canadians' concerns about congestion and pollution in major urban areas might weaken their preference for car travel. Even a small shift in private car use could have a dramatic impact on the public modes of passenger transportation.

- Globalization could lead to increasing international travel. There is already some indication that this might happen. For example, between 1980 and 1990, international trips increased at an average annual rate of 5.2 percent, while domestic trips rose by 1.9 percent.
- Improvements in telecommunications technology could reduce the demand for face-to-face meetings and, therefore, lessen the demand for travel (especially business travel). On the other hand, the possibility of worldwide mobile personal communication links may enable business people to "take their office with them," thereby increasing travel and mobility.
- New forms of travel, such as advanced supersonic aircraft, intelligent vehicle-highway systems, faster rail systems and high-speed ferries, could influence the way Canadians travel.

Based on the experience of the past 30 years, we doubt that there will be dramatic change in the way Canadians travel in the next 30 years. Markets will continue to change, but the providers of passenger transportation services are unlikely to face dramatic shifts in demand or radically new forms of travel in the near future.

Nevertheless, because predicting the future accurately is virtually impossible, we recognized early on that our proposed framework for the passenger transportation system had to provide enough flexibility for industry, governments and travellers to adjust to major changes, should they occur.

## CONCLUSION

Canada faces many opportunities and challenges, some of them similar to those of other countries. Canadians should understand how other countries are adjusting their passenger transportation systems. In other ways, Canada faces challenges and opportunities that are special — products of its unique history, geography, climate and culture. Canadians need solutions tailored to Canada's problems, issues and concerns.

# ENDNOTES

1. After the enactment of the *National Transportation Act of 1967*, the government made accompanying changes to the *Railway Act*, and Canadian railway companies enjoyed a more liberalized environment than their U.S. counterparts until U.S. substantial economic deregulation of rail in the early 1980s.

2. As indicated in endnote 2 of Chapter 1, the range is due to intercity car travel being defined as either car trips over 80 kilometres in one-way distance, or all highway use by cars. See Notes to Chapter 1 and Notes to Chapter 2, in Volume 2 of this report.

3. Source for data on total government employment in transportation and communications: Statistics Canada, *Public Sector Employment and Remuneration 1990/91*, Catalogue No. 72-209, October 1991. This source does not report data for transportation employment alone.

4. For a more detailed description of intercity passenger transportation, see Volume 2, Chapter 2, of this report and Chapter III of *Getting There: The Interim Report of the Royal Commission on National Passenger Transportation* (Ottawa: Supply and Services Canada, 1991).

   Note: For both the domestic and international cases, intercity trips are defined as trips over 80 kilometres one way in this and the following section. This excludes many non-urban trips, especially by car, domestically, and many "cross-border shopping" international trips.

5. "Intercity" may be defined in different ways, and estimates of the amount of travel by car in particular are subject to considerable margins of uncertainty. Thus, our estimates of car travel, and of other means of transportation, in total intercity trips or in total passenger-kilometres travelled, should be viewed as approximate. See further discussion in Volume 2, Chapter 2 of this report.

# CHAPTER 3

# COSTS OF TRANSPORTATION AND WHO PAYS: TRAVELLERS OR TAXPAYERS?

## INTRODUCTION

An essential first step in examining transportation issues and in making sound decisions on passenger transportation is to understand the full costs of transportation today, including accident costs, the cost of damage to the environment, and the cost of providing infrastructure. Further, if travellers are to cover the costs of providing and maintaining the passenger transportation system — as we will recommend — it is important to know what proportion of total costs travellers currently pay and what proportion is borne by others.

Some Canadians may be concerned that transferring the costs borne by others to those who travel might increase costs of travel, discourage use of the passenger transportation system and slow economic growth. We remind them, however, that these costs are already being borne by Canadians. Funding transportation through charges, rather than taxes, would not, by itself, alter the total costs Canadians pay. Furthermore, we believe that the changes we recommend in how Canadians should pay for the passenger transportation system will also lead to changes that will lower the total costs of the passenger transportation system.

In our approach, travellers and carriers would pay full costs, but these costs would be based on principles of efficient investment and pricing. Travellers would not be paying for a passenger transportation system that is wasteful because it has too much or too little capacity, or capacity of the wrong type and in the wrong place. Travellers and carriers would be able to purchase services at the lowest possible prices for the greatest benefit.

The remainder of this chapter is devoted to estimating the comprehensive costs of the current system — a system that is not as efficient as it could become. Our figures, therefore, overestimate the total costs of transportation and the additional costs to be paid by travellers, but these figures are a key starting point in understanding the current system and the potential for change. In referring to costs paid by travellers, we include charges to carriers that will be passed on to travellers in the fares they pay.

## TODAY'S SUBSIDIES AND COSTS — HIDDEN AND DIRECT

Currently, taxpayers knowingly support the transportation system through direct subsidies and unknowingly through hidden subsidies. Direct subsidies are those that governments show in their budgets as amounts transferred to carriers or travellers from the taxpayers. Hidden subsidies are those that are less visible to the public.

Hidden subsidies hamper the development of rational transportation policy. During our public hearings, several interveners expressed frustration about hidden subsidies in the passenger transportation system. These subsidies may mislead governments trying to make decisions based on efficiency and competition, and certainly lessen the public's ability to assess policy decisions. If, for example, a government must choose between building a road for a certain route or providing rail service, it will be unable to make the wisest choice (the best transportation at the least cost to the traveller) if the true costs of road and rail are not known.

The House of Commons Standing Committee on Transport also recognized the problems associated with hidden subsidies. In its March 1992 report, *High Speed Rail: The Canadian Concept*, in Recommendation 9, the Committee stated ". . . considering it is essential to more accurately determine the amount of subsidy for each mode, the Royal Commission on National Passenger Transportation should place particular emphasis, in its Final Report, on the identification of the levels of hidden subsidization within each mode."

Hidden subsidies, direct subsidies, special advantages or disadvantages resulting from government action can arise in a number of ways.

*Transportation infrastructure costs:* Governments may provide infrastructure (terminals, links and traffic control — see Table 2-1 in Chapter 2) to a mode free of charge or for charges that do not recover the full costs. In these cases, the subsidy comes from the taxpayer and appears in government budgets. How the subsidy should be apportioned among different groups of travellers may be subject to debate.

*Environmental costs:* At present, governments allow transportation activities to cause damage to the environment without charging carriers or travellers for these damages. This is equivalent to a subsidy from today's public, who experience the adverse effects on the environment, and possibly a subsidy from future generations as well. Other than costs of some clean-up work performed by governments, which are included in their budgets, most of the costs associated with environmental damage (for example, discomfort or ill health) do not appear in government accounts.

*Accident costs:* Travellers do not pay all the costs associated with accidents. Some of the costs are paid for by public health insurance systems that do not recover, or only partially recover, the costs from transportation users and carriers.

*Special transportation taxes and fees:* These taxes and fees are specific to transportation, but are not designated as charges for infrastructure, environmental damage or accidents. They include fuel taxes, and vehicle, carrier and drivers' licences. In our view, general consumption taxes, such as provincial sales taxes and the Goods and Services Tax, do not constitute a special cost or disadvantage for a particular passenger transportation mode, since such taxes are applied broadly in the economy. These general taxes are not included in our analysis. But special taxes and fees on transportation fares, or on inputs such as fuel, are of interest because they may give one mode a financial advantage over another.

General property taxes applied on the same basis to all industries would not be included, but differentials in the application of property taxes — for example, levying such taxes on rail rights-of-way but not on road — should, in principle, be recognized. Where special taxes — or differentials due to above-average rates of general taxes — exist, they should be considered to offset hidden subsidies associated with infrastructure costs, environmental damage and accident costs currently paid by taxpayers.

We have estimated the costs related to transportation infrastructure, environmental damage, accidents, the revenues from special taxes and fees, and payments of direct subsidies. We use these estimates to consider how governments treat different types of passenger transportation.

## SYSTEM-WIDE COSTS

As we stated earlier, people will not be able to make sound transportation decisions unless they have comprehensive figures for the costs of travel in each mode. To our knowledge, such figures have never been calculated in Canada. We have estimated the system-wide costs of transportation and how much users currently pay, and how much others pay (Table 3-1 and Chart 3-1). The total costs borne by others provide an estimate of total subsidies, both hidden and direct.

"Users" are travellers, vehicle owners and carriers. "Others," who pay for costs of transportation although they may or may not be using the transportation system, are taxpayers (who cover the financial costs paid by governments) and the general public (who directly bear most environmental damage costs).

We caution, however, that our estimates of costs are imprecise because of the current lack of data. Nonetheless, we believe that our figures are useful to begin gauging the true costs of transportation in the different modes. It will be important for governments to develop better estimates before making future policy decisions, including setting charges for travellers.

We present these system-wide averages as an introduction. Later in the chapter, we provide estimates of the costs for particular routes, which may be more relevant to some policy decisions than the system-wide averages.

A simple basis for comparing costs between modes is the cost per passenger-kilometre, that is, how much it costs to carry one passenger one kilometre, or total costs divided by total passenger-kilometres. We recognize that cost per passenger-kilometre is not a perfect basis of comparison, because transportation by different modes is not always comparable. For example, when people travel by ferry and car, the costs are those of moving a passenger "accompanied by an average amount of car." On the other hand, the bus, airplane and train costs are only for passengers and their personal baggage. On some carriers, food is provided; on others, passengers pay extra for food. The average trip also differs across the modes. Air trips are generally much longer and ferry trips much shorter than those taken by road or rail. System-average costs per passenger-kilometre are therefore not fully comparable, but they do provide a start.

The costs of travel by different modes vary substantially. This is reasonable because some modes are more expensive to operate and provide more services than others. We are particularly interested, however, when costs not borne by users differ substantially by mode of travel. These variations indicate that government policy today is not neutral across modes and gives some modes competitive advantages over others.

## INTERPRETING TABLE 3-1 AND CHART 3-1

Table 3-1(a) illustrates the components of average costs, in cents per passenger-kilometre, for domestic travel by the different modes in 1991. Table 3-1(b) estimates the total costs of domestic intercity travel, in millions of dollars, for the different modes. Our total cost estimates for car travel in this chapter and in Chapter 18 refer to all car travel on highways, rather than the narrower definition of intercity car travel restricted to trips of 80 kilometres or more used in estimates in other chapters.

The components of system-average costs, Table 3-1(a), are also presented graphically in Chart 3-1.

The costs borne by users (including special transportation taxes and fees paid by travellers) are stacked so that the overall height of the bar on the left indicates the total costs borne by travellers.

The costs borne by others are stacked to form the bar on the right. The total length of the bar represents the gross cost borne by others, before subtracting revenue received from special transportation taxes and fees. The distance below zero at which the bar starts is equal to the amount received. (The segment below zero represents revenues from the same special taxes and fees that are shown as a cost to users by the segment at the top of the left bar.) Therefore, the total height of the bar above zero shows the net cost borne by others.

The height of the users bar may be compared with the height (above zero) of the others bar to see the relative net contributions of users and others to the means of transportation in question.

We use estimates for 1991 to provide a current view of costs. Where 1991 data on costs and system use are not available, our figures are based on older data projected forward to 1991. This increases the margin of error in the estimates. In addition, we have attempted to smooth out the impact of the recession; our estimates are for normal costs and revenues in 1991. The table shows system-average cost estimates per passenger-kilometre to the nearest tenth of a cent, and total cost estimates to the nearest million dollars. Later tables show route costs to the nearest dollar. This is done in order to show some small cost components that would disappear if the table showed numbers that were rounded to the extent appropriate for the larger cost components. All estimates, however, should be viewed as approximate.

The cost estimates are documented in Volume 2 of this report. In the following paragraphs, we briefly explain the meaning of each component of the costs.

*Table 3-1(a)*

**ILLUSTRATIVE SYSTEM-WIDE ANNUAL COSTS OF INTERCITY DOMESTIC TRAVEL, PAID BY USERS AND OTHERS, 1991, IN 1991 DOLLARS**

| Average costs: cents per passenger-kilometre | | | | | | |

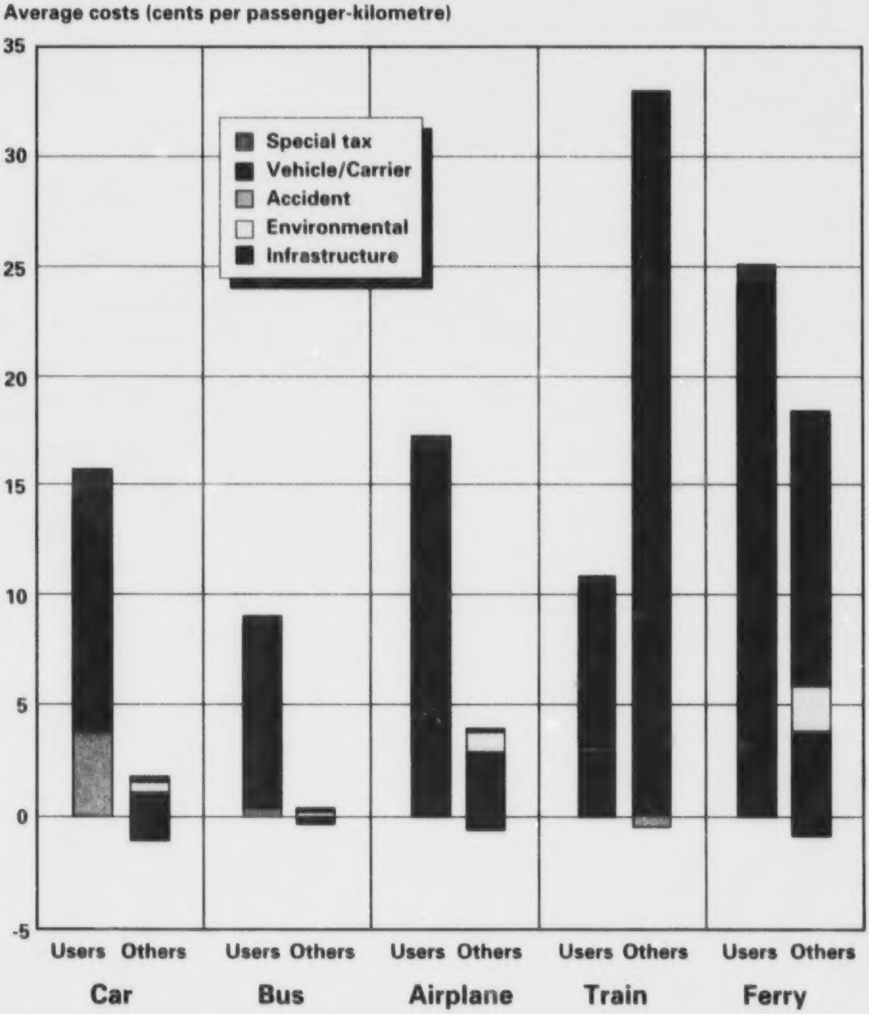
Note: **In order to illustrate smaller components, averages are shown to the nearest tenth of a cent and totals to the nearest million dollars. In general, cost estimates are approximate and are not accurate to this level of precision. See text.**

*Chart 3-1*

*ILLUSTRATIVE COMPREHENSIVE SYSTEM-WIDE COSTS OF INTERCITY DOMESTIC TRAVEL, PAID BY USERS AND OTHERS, 1991*



Note: The chart is a graphic representation of Table 3-1(a). Any negative components of the costs borne by others are represented by shifting the others bar below the zero line.[1]

For purposes of our cost analysis, "infrastructure" consists of terminals, links and traffic control (including police systems) not provided by carriers. It excludes most bus terminals, some ferry docks, and some passenger rail stations that are provided by carriers. The total cost for transportation infrastructure is the sum of the estimated capital and operating expenses. (Where infrastructure is provided by a carrier, these costs are built into vehicle/carrier costs.) The others portion is the total cost minus the amount covered by charges paid by travellers and carriers.

The estimates of infrastructure costs include depreciation and interest on the investment in the facility. When the value of land is also a significant part of the total value of the facility, an interest charge on the value of land is also included in costs. The basis for the infrastructure cost estimates is discussed further in Chapter 5.

Infrastructure costs to travellers and carriers are charges levied by the infrastructure providers (primarily governments) to help cover the costs of building and operating them. For air travel, charges consist of the Air Transportation Tax, airport landing and terminal fees, and rent for airport space used by carriers. For rail travel, Canadian National Railways and Canadian Pacific Ltd. charge VIA Rail for use of track and other services (such as dispatch). For road travel, there are road tolls on one highway in British Columbia, but the revenues are so small relative to the total road system that they have not been included in the table.

Some infrastructure costs may be higher than necessary, in part because bigger or more elaborate facilities than travellers require have been provided. In this chapter, we set out existing costs; in subsequent chapters, we discuss whether and how some of these costs might be reduced.

Environmental costs result from the environmental damage caused by air and noise pollution from vehicle and carrier operations. As we pointed out earlier, the public generally bears these costs, which do not appear in government accounts. Environmental costs borne by others are the estimated values of the total damage and unpleasantness associated with vehicle emissions and noise (Chapter 7).

Accident costs include a valuation of death and injury, health care costs and property damage. Travellers pay accident costs through their insurance premiums and through injuries and damage not covered by personal insurance or government health insurance. Accident costs borne by others are government health care costs that are not recovered from self-financing vehicle insurance plans or from carriers (Chapter 8).

Special transportation taxes and fees include fuel taxes and vehicle, carrier and drivers' licence charges. These special transportation taxes and fees are different from other government charges to travellers, such as the Air Transportation Tax and tolls, since governments do not directly apply the revenues raised from the special taxes to cover the costs of transportation infrastructure, environmental damage or accidents. Therefore, our table shows special taxes and fees as a separate category of charge.

We believe special taxes and fees should be considered an offset to infrastructure, environmental costs and accident costs borne by the taxpayer or the public. We have, however, adjusted the fuel tax components of special taxes before including them in the table, since every province except Quebec exempts fuel from the general provincial sales tax. For these provinces, we consider only that part of the fuel tax in excess of the provincial sales tax rate to be a special tax on transportation.

In Table 3-1 and Chart 3-1, we show the special taxes and fees as a component, along with charges for infrastructure, environmental damage and accidents, of total costs paid by users. Since special tax revenues are not used to finance a particular type of transportation expenditure, they may be viewed as a general offset to costs borne by others. Hence, revenues from taxes and fees are shown in the others column with a negative sign. The resulting zero in the total column shows that these taxes do not increase the total costs of passenger transportation, but rather are a mechanism for determining who is paying what.

Vehicle/carrier costs are the capital and operating costs incurred by owners of private vehicles or by carriers providing public transportation. These costs also include infrastructure costs when carriers provide their own facilities, for example, when bus or ferry companies own their own terminals. Vehicle/carrier costs borne by users are calculated using fares charged to travellers or the costs of buying and operating a car, and subtracting charges to travellers and carriers for infrastructure, environmental costs, accident costs and special taxes and fees. In our estimates, vehicle/carrier costs also include costs arising from equipment requirements designed to lessen pollution or increase safety. (Such costs might alternatively be included under environmental or safety costs, but are difficult to separate from the basic cost of the vehicle.)

Vehicle/carrier costs borne by others represent direct subsidies to carrier operators. (In some cases, it might be argued that part of the direct subsidy should be viewed as covering infrastructure or other charges paid by the carrier, but we show the full direct subsidy as vehicle/carrier costs borne by others.)

Differences in the vehicle/carrier costs of each type of carrier, including cars, may not be considered relevant for government transportation policy decisions as long as travellers pay the costs and as long as monopoly pricing by carriers is not a concern. On the other hand, these vehicle/carrier costs form the largest component of total costs; it is useful to keep them in mind when considering whether costs currently borne by others are important or unimportant in the total picture for a given mode of travel.

In Table 3-1, total costs for users, others, and in total, are sums of their components. As mentioned earlier, we use total costs borne by others as our measure of the net subsidy from governments and the public to each means of transportation. The total of costs borne by users and others is, of course, our measure of the overall costs of providing each means of transportation. When we refer to "total costs," we are referring to this sum.

## CONCLUSIONS: TABLE 3-1 AND CHART 3-1

### Average Costs and Subsidies

Bus travel is the least costly mode. The average total cost of bus travel is 9.5¢ per passenger-kilometre. We estimate that bus travellers pay all but 0.4¢ per passenger-kilometre of this. Bus travellers receive the least subsidy per passenger-kilometre of all travellers.

Car and airplane travellers receive a somewhat larger total subsidy than bus travellers per passenger-kilometre. The general taxpayer and the public subsidize car travel by an estimated 1.6¢ per passenger-kilometre and air travel by 3.8¢ per passenger-kilometre. These subsidies cover infrastructure, environmental and accident costs not paid by users, plus small direct subsidies paid for air travel in some provinces, less special taxes collected.

The largest gaps between users and total costs are for train and ferry travel — 33¢ per passenger-kilometre for train and 17.4¢ per passenger-kilometre for ferry. This is due to large, direct subsidies from taxpayers to travellers using passenger rail and some ferry services (these direct subsidies are shown as vehicle/carrier costs borne by others).

### Environmental Costs

Our figures for environmental costs are based on high estimates for damage associated with carbon dioxide and other pollutants that affect air quality relative to the ranges of estimates available. We did this so the overall subsidy comparison would err on the side of favouring the less-polluting modes of passenger transportation. Although important, environmental costs do not turn out to be large relative to total costs for any of the modes. Environmental costs for bus travel are the lowest.

Some observers believe that car travel causes a great deal more pollution than train or bus travel. When car pollution is viewed in terms of the average per passenger-kilometre, however, its costs are not always the highest. There are several reasons for this. Regulations regarding car exhaust emissions have encouraged greater reductions in the amount of pollutants emitted by cars than by buses or trains. In addition, when train equipment is old, the occupancy rate is low, or dining and sleeping services as well as basic seating are provided, trains may use as much or more fuel per passenger-kilometre as cars.

Nevertheless, cars account for most pollution, because most travel is by car.

### Accident Costs

Accident costs per passenger-kilometre are much higher for travel by car than they are for any other mode. These costs account for almost one quarter of the total costs of car travel. Travellers bear most of these costs through insurance premiums and by paying for uninsured losses they suffer. Accident costs borne by others through unrecovered health care system costs are estimated to amount to 0.1¢ per passenger-kilometre. Costs of accidents borne by others for bus, air and train travel are negligible.

### Total Costs

Table 3-1(b) provides estimates of the total costs, in millions of dollars for each mode of transportation. In the preceding discussion, we have focussed attention on differences in average costs, especially those borne by others. The average costs borne by others largely represent subsidies from governments to the various modes less special taxes and fees collected by governments. As Table 3-1 shows, governments currently treat the various modes of travel differently.

Total cost estimates are also of interest, however, as they indicate the overall amounts spent on each mode of transportation. While the average subsidy rates for car and air travel are relatively low, the large numbers of kilometres represented by car and air travel mean the total subsidies to these modes account for the bulk of the estimated $5.0 billion total subsidy to domestic intercity passenger travel (estimated at $3.4 billion for car and $0.9 billion for airplane).

## COSTS: SOME SAMPLE ROUTES

In addition to estimating comprehensive, system-wide costs, we have estimated the costs per one-way trip for four intercity routes that represent different combinations of length and passenger volume:

- Toronto to Montreal — a high-volume, medium-distance route (Table 3-2 and Chart 3-2);
- Saskatoon to Halifax — a long-distance route consisting mainly of medium-volume segments (Table 3-3 and Chart 3-3);
- Val d'Or to Montreal — a medium-distance route including low-volume segments (Table 3-4 and Chart 3-4); and
- Vancouver to Toronto — a long-distance route with high-volume air travel (Table 3-5 and Chart 3-5).

(Costs for a route that includes a ferry segment are shown in Chapter 18.)

### INTERPRETING TABLES 3-2 TO 3-5 AND CHARTS 3-2 TO 3-5

In these tables, our estimates for total and users' vehicle/carrier costs are based on averages of costs and revenue yields for routes of similar volume and distance. They do not reflect actual carrier costs or revenues on the particular routes.

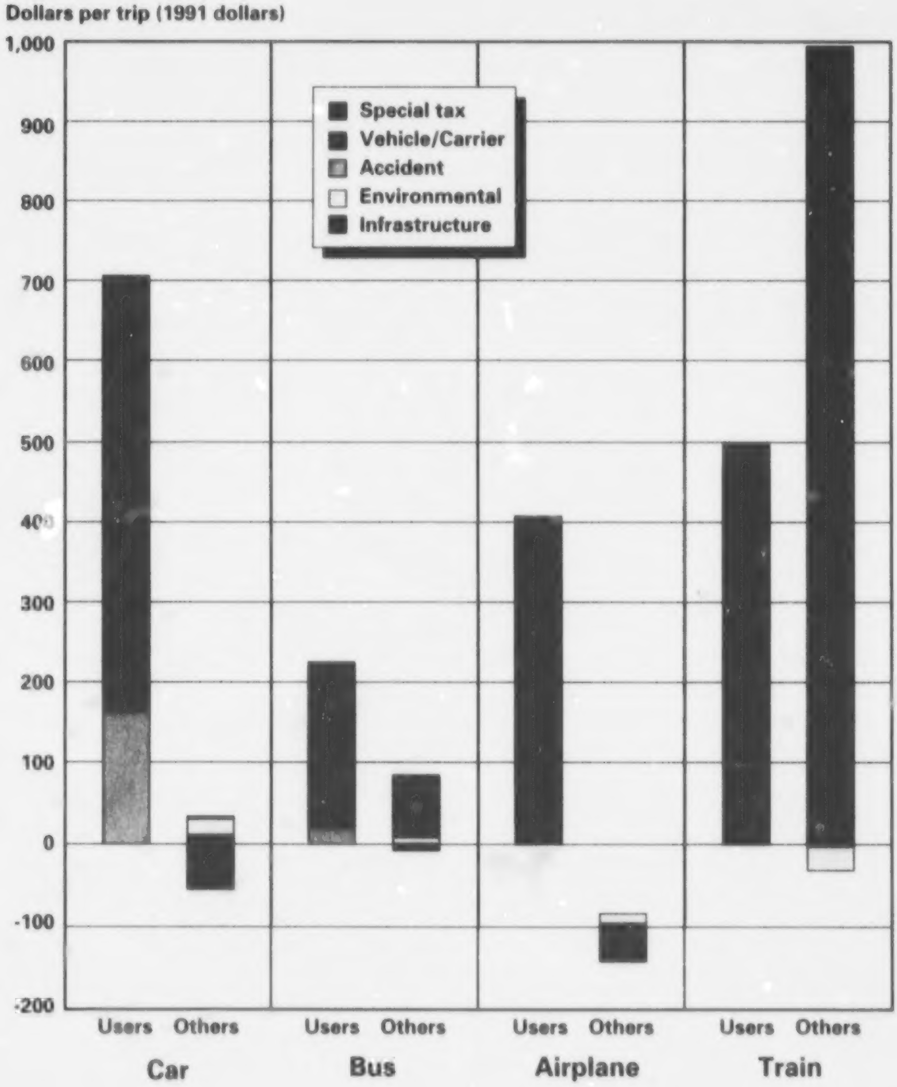
*Chart 3-5*

*ILLUSTRATIVE COMPREHENSIVE COSTS PER PASSENGER, DOLLARS PER TRIP, VANCOUVER TO TORONTO*



Note: The chart is a graphic representation of Table 3-5. Any negative components of the costs borne by others are represented by shifting the others bar below the zero line.[1]

In addition to showing estimates for the components of the costs for each means of transportation on the route in question, the tables show the overall average cost per passenger-kilometre, borne by users, others, and in total. These average per-passenger-kilometre costs, calculated using the route lengths for each different means of transportation, provide a basis for comparing their operating characteristics. Because the route length between two centres can differ for different means of travel, for some purposes — for example when considering the overall amount of subsidy for travel between two points — it is of interest to compare per-passenger-kilometre costs on a standardized basis. We have used the air distance for this standardized comparison.

### Cross Subsidies

The difference between user and total vehicle/carrier costs on a route includes the impact of cross subsidies. Cross subsidies occur when a carrier uses revenues from profitable routes to cover part of the costs of unprofitable routes. For example, under provincial regulation, bus companies must provide service on low-volume routes in order to be granted high-volume routes; they subsidize the former with the profits from the latter. In our route tables, cross subsidies (the difference between estimates of total vehicle/carrier cost for the route and the vehicle/carrier share of fare revenues) are included in vehicle/carrier costs borne by others since other travellers on other routes pay these cross subsidies.

Some governments provide direct subsidies to buses on a small portion of total bus routes; these subsidies averaged across all bus travel are shown as vehicle/carrier costs borne by others in the system-wide costs. Cross subsidies do not appear in the system-wide average table (they cancel out). But, in the route tables, the amount in the others column for vehicle/carrier costs represents any direct subsidy plus any cross subsidy.

For bus routes of the Toronto to Montreal type, this amount is estimated to be negative. This is because although we estimate that the traveller pays an average of $36.60 toward vehicle/carrier costs for this type of trip, the average cost to the bus company is $33.60. In this case, there is no direct government subsidy and, therefore, the minus $3.00 shown for vehicle/carrier costs borne by others is a potential cross subsidy from passengers on this type of route to those travelling other routes operated by the same company.

On the other hand, for the Vancouver to Toronto type of route, we estimate that, given the lower bus fares for through-travel, bus passengers pay less than the average costs (average costs include a share in company overhead). In other words, they receive a cross subsidy. For air routes of the Vancouver to Toronto type, the vehicle/carrier situation is the reverse; on these air routes, passengers are estimated to contribute more than the average amount to profits. In other words they pay a cross subsidy.

In the case of trains, the entire amount of vehicle/carrier costs borne by others is an estimate of the direct taxpayer subsidy attributable to that route.

## CONCLUSIONS: TABLES 3-2 TO 3-5 AND CHARTS 3-2 TO 3-5

### Transportation Infrastructure Costs

On the high-volume Toronto to Montreal route, special taxes and fees for car and bus travel equal or exceed the costs of the road used. These special taxes and fees, however, do not fully offset the total costs of infrastructure, environmental damage and accidents. For air travel, infrastructure charges do not come close to covering costs for any of the domestic routes considered. On the medium-volume and lower-volume routes, as well as for the system-wide averages, special taxes and fees for car travel do not fully cover our estimate of the total capital, maintenance and other costs (including traffic policing) of roads.

### Environmental Costs

Estimates for environmental costs of train and airplane emissions per passenger-kilometre differ by route, reflecting different vehicle occupancy rates and the use of different equipment. As well, our estimates assign a higher cost to some pollutants if they are released during the summer in areas that already have problems with air quality (such as the Windsor to Quebec City corridor and the Lower Fraser Valley regions).

In terms of environmental costs, the train on the high-volume Toronto to Montreal route incurs costs that are somewhat lower than the car's and considerably lower than the airplane's, although higher than the environmental costs of bus travel. On this route, train equipment is newer and more fuel efficient, the number of seats per train is higher, and train occupancy rates are high. (In Chapter 7, we consider how the train's effect on the environment might improve with different equipment.) On the lower-volume rail routes, the train has considerably higher environmental costs than those of car, airplane or bus travel.

The environmental costs of airplane travel can be lower than those of car travel on direct longer-distance routes, as shown by the Vancouver to Toronto example. In aircraft operation, much of the noise, fuel consumption and emission of carbon dioxide and other pollutants occurs while waiting for or during take-off. For longer direct flights, therefore, environmental costs are proportionately lower than for short flights.

### Total Subsidies

On all the routes considered, bus travellers come closest to paying total costs if the cross subsidies among bus passengers are set aside. The total subsidy is larger for car travellers, but still not a large portion of total costs.

Total subsidies for air travel (excluding the impact of cross subsidies among routes) are larger than for car travel on most routes, and represent an appreciable share of total costs even on high-volume routes.

Subsidies to passenger rail include direct subsidies from taxpayers and some environmental costs. Transportation infrastructure costs are paid by the rail carrier for track use and train traffic control.

Even on the Toronto to Montreal route, which for the train has the lowest amount of direct (vehicle/carrier) subsidy from others and has the lowest environmental costs, the passenger rail subsidy is substantially larger than total subsidies to car or air travel. On the other routes, train costs borne by others (primarily the federal taxpayer) are many times larger than the subsidies to car or air travel.

## CONCLUSION

Only the bus comes close to paying its way in the passenger transportation system. Bus travellers pay almost as much in special taxes and fees charged by governments as the costs of government-provided infrastructure, environmental costs and accidents incurred by bus travel.

Both car and airplane travel have a competitive advantage over the bus, because car and air travellers pay less of the full cost of their transportation. Government charges for car and airplane travel do not fully cover infrastructure and environmental damage costs. (Environmental damage by car, airplane and bus has been limited by regulation, and car, airplane and bus travellers do pay the costs of equipment required to comply with the regulations.) Car travellers also do not fully pay for the costs that car accidents impose on the health care system.

Overall, subsidies from taxpayers for rail and ferry are the largest, on average, per passenger-kilometre.

The following chapters contain recommendations that will change many of the above costs and who pays them. In Chapter 18 we will look again at these estimates of comprehensive costs when we consider the overall impact of our recommendations.

# ENDNOTES

1. In the system-average table and chart, the only negative component of the others' costs is the special transportation tax/fee. This was represented in Chart 3-1 by a shift down in the others bar by the amount of special transportation tax/fee revenues. For the individual routes, cross subsidies are another potential negative component of others' costs.

   When users pay more than the vehicle/carrier costs associated with the route used, the excess is considered a contribution from users to others (other travellers). When this occurs, the base of the others bar is shifted below the zero line by an amount equal to the sum of revenues from special taxes and fees (a negative component of others costs) and of negative cross subsidies (cross subsidies available for other travellers).

   For example, for airplane travel on the Vancouver to Toronto route (Table 3-5 and Chart 3-5), the others bar starts at –142, the sum of –19 from special taxes and –123 from cross subsidy.

   Only the positive components of others' costs are shown as explicit segments of the bar. For Vancouver to Toronto airplane travel, the positive components add to 57, which is the vertical height of the bar above its –142 base.

   In a few cases for the individual routes, the negative components exceed the positive components of costs borne by others, resulting in negative net costs. In such cases, the top of the others bar, which indicates net costs borne by others, is below the zero line. For example, again for the Vancouver to Toronto airplane travel case, Table 3-5 shows net costs borne by others of –85. The top of the others bar for airplane travel in Chart 3-5 thus lies below the zero line at –85.

# CHAPTER 4

# NEW DIRECTIONS: FOUNDATIONS FOR A PASSENGER TRANSPORTATION FRAMEWORK

## INTRODUCTION

In Chapter 1, we discussed our approach to providing Canada with a new passenger transportation framework for the 21st century that would lead to more consistent, coherent and economically sound transportation decisions. In this chapter, we set out the foundation for this new framework, discuss its implications for governments, travellers and carriers, and suggest transition mechanisms to get from the current situation to our proposed framework.

## FOUNDATIONS FOR A NEW FRAMEWORK

We believe that the main goal of Canada's intercity passenger transportation system should be straightforward — to move people to where they want to go. Travellers should be able to choose the transportation services they want, get what they pay for, and pay for what they get.[1]

In the past, governments have used the transportation system to pursue other public policy goals. We believe that the passenger transportation system should not be used by governments in this way, today or in the future. As well, the traveller should not be asked to pay for the implementation of broad, national goals that are properly the responsibility of the general taxpayer.

In this report, we spend much time and space discussing charges to travellers. These include fares, fees, fuel taxes and licences. We realize that many of our recommendations may seem to advocate a greater financial burden on a public already unhappy about prices and taxes. Although this may be the appearance, it is neither the reality, nor does it represent the fundamentals of what our approach will achieve. Although Canadians may be unhappy with transportation-related prices and taxes, and be unwilling to see them increase, they are nevertheless already "paying" all of the costs of transportation in some way. For example:

- taxpayers pay a substantial portion of the cost of the infrastructure used by travellers and subsidize some carriers directly;
- people with asthma pay for low-level ozone concentrations in cities through discomfort and poor health;
- commuters pay for traffic congestion in lost hours;
- homeowners pay for car, truck and airplane noise when they cannot enjoy their homes and yards; and
- everyone pays for the general degradation of the environment.

What we advocate in this report is that those who supply and those who use passenger transportation services pay the costs of their activities. Those who do not use passenger transportation services should not have to pay for them. In addition, those who pay in non-monetary ways should gain relief or compensation. This, we believe, would be a much more equitable system than the one we have today. Our recommendations should also result in a more efficient passenger transportation system and a lower financial burden on Canadians, and would enable governments to reduce taxes with the money saved.

## OBJECTIVES

We believe that Canadian passenger transportation policy will be in the forefront worldwide if it leads to a passenger transportation system that is safe, protective of the environment, fair and equitable to taxpayers and all groups of travellers, and efficient.

Therefore, we **recommend** that:

**4.1 Transportation policies be guided by the following four objectives:**

**(a) safety;**

**(b) protection of the environment;**

**(c) fairness to taxpayers, travellers and carriers; and**

**(d) efficiency, so that services are provided only where the benefits to the individual traveller equal or exceed the cost, and given levels of service are provided at the lowest possible cost.**

Efficiency may strike some as a rather abstract objective, of interest primarily to economists. But this is not the case; efficiency means making the best use of one's resources and opportunities or, more simply, avoiding waste. As householders know from managing their family's finances, avoiding waste will get the most out of the family's income, or — in economic terms — will maximize its benefits, given its resources.

There are three types of waste to avoid. The first type of waste occurs when people spend more than is necessary to obtain goods or services. The parallel situation in transportation policy is when more is spent than is necessary — using a more expensive capital facility than necessary, or employing more people than necessary — to produce transportation services.

The second type of waste occurs when the householder would be better off not buying (or buying less of) the particular goods or services, and instead using the money on something else. The parallel situation in transportation occurs when governments decide to spend money on a particular transportation service, even though an alternative transportation service would be more worthwhile, or when Canadians would be better off using the money to obtain other things.

Thirdly, not spending money can also, in some cases, be a source of waste. Not spending on maintaining a car or house may require a higher level of spending in the future. For example, not spending money on a new furnace may be more than offset by higher fuel bills over time and thus constitute waste. In transportation, failure to devote sufficient resources to maintaining a road may result in having to spend much more in the future, or in a major reduction in the usefulness of the road. Failing to provide an airport in a community that has grown substantially may lose an opportunity to save major amounts of time for people travelling to and from the community. If people value the time savings sufficiently, the lack of spending on the airport would constitute waste or inefficiency.

Choosing efficiency as one of the objectives to guide passenger transportation policy simply recognizes that passenger transportation systems that avoid waste will contribute the most to Canadians' economic well-being.

Protecting the environment and maintaining safety are part of Canadians' present and future well-being. The efficiency objective can, therefore, be broadly interpreted to include achieving adequate levels of safety and environmental protection. This was the approach we took in our Interim Report. For greater clarity, we identify environmental protection and safety as separate objectives.

What about other objectives? We agree with those Canadians who told us that nation-building and regional development should be objectives of the various levels of government. We also believe that these objectives can be pursued through a variety of policies.[2] We do not agree, however, that passenger transportation policies should be guided by objectives of nation-building and regional development. Our reasons are as follows:

*Nation-building:* In general, the passenger transportation system is mature, and most Canadians are well served by a number of modes. We do not believe that any single project, route, network or mode is likely to stand out today, as the transcontinental railway once did, as a symbol that unites Canada. We doubt that any new passenger transportation mega-project would contribute to building the nation, beyond its economic contribution, which can be assessed using normal criteria.

To be sure, there is a need to bind Canada together, but we believe that individual Canadians — aided by volunteer organizations and government departments other than transportation departments — can most effectively carry out the task of binding the nation together.

*Regional development:* We recognize that passenger transportation infrastructure and services can play a vital role in the development and functioning of national and regional economies. As we suggest in our efficiency objective, the benefits of infrastructure and services to travellers should be compared with costs when decisions on passenger transportation projects and services are made. From our research and consultations, we concluded that the separate and additional regional development benefits that may be derived from government expenditures on passenger transportation are unlikely to be substantial and should not be used to guide passenger transportation policies. Our reasoning is threefold.

First of all, passenger transportation projects and services that are likely to contribute to regional development will pass the benefit-cost test under the efficiency objective. The benefits that regions gain from passenger transportation projects, other than those associated with benefits to travellers, are generally limited. In almost all the populated parts of Canada, the basic passenger transportation infrastructure already exists. Adding more or improved infrastructure, if that does not increase traveller benefits more than costs, is a questionable means of stimulating development. Half-empty roads and underused airports would be the likely result.

Secondly, we recognize that regions may realize short-term economic gains from construction activities associated with passenger transportation projects, but these activities do not have the same economic effect today as they did in the past. Construction is increasingly automated, and equipment and materials are often purchased from other regions.

Furthermore, non-transportation projects also require construction. We do not believe that transportation projects should be singled out by governments for subsidies in order to carry out regional development objectives for which they are not designed.

Finally, under the terms of our mandate, we are to consider long-term passenger transportation policies for 30 or more years into the future. We have therefore focussed on the benefits that will continue many years after projects are completed. Projects not supported by a review of the needs of travellers, and the benefits to them, place a long-term drain on financial resources that could otherwise be positively used for the development of Canada or its regions.

Therefore, we **recommend** that:

**4.2 Governments pursue nation-building and regional development objectives through other programs, rather than using the passenger transportation system.**

If governments decide to pursue nation-building, regional development or any other objectives through the passenger transportation system, taxpayers in the jurisdiction that makes the decision should pay the cost of such programs, rather than those who use the passenger transportation system. As well, governments should let the public know why they are providing such subsidies and at what cost. We strongly believe that the use of subsidies should be the exception, not the rule.

## PRINCIPLES FOR TRAVELLERS

How can we translate our four objectives into operational principles? Our broad goal is to move people to where they want to go, using any means for which they are prepared to pay, but avoiding waste. That is, we want a passenger transportation system that is safe, protects the environment, is fair to taxpayers, travellers and carriers and is efficient.

In many circumstances, market forces are a reliable guide for achieving the best use of resources. Market prices provide important signals about the kinds of travel services that travellers want, and competition provides an important discipline on those who provide these services. To prosper in a competitive environment, firms must respond to travellers' preferences, cut costs, improve productivity and innovate — all of which contribute to increased efficiency. Relying on market forces will also contribute to fairness. Individual travellers will pay for the choices they make, and they will pay the full costs of their travel without help from the taxpayer or other travellers.

The principles flowing from our four objectives have four thrusts. First, for much of Canada's history, transportation has played a nation-building or developmental role and Canadians have come to regard it as a public service like national defence, rather than a business like a hotel or restaurant. Too often in transportation, there has been a failure to appreciate the benefits from competitive markets — and the costs of restricting competition. Therefore, one of the main thrusts of our principles is to achieve the benefits from treating transportation like any other business where people buy and sell services, instead of as a government function. We have to identify areas, both in the activities of carriers and the providers of infrastructure, where there would be benefits from a greater reliance on competitive markets.

Second, treating transportation as a business will not work in all circumstances. Therefore, a second thrust of our principles must be directed at those areas where the market does not work very well — where it would not provide adequate levels of safety or environmental protection or where it would not be efficient or fair to travellers or taxpayers.

If carriers and providers of infrastructure do not have to take account of the impact of their activities on the environment and the health care system, the prices they charge can result in Canadians travelling by polluting or dangerous means of travel because it is cheap. Governments can correct this by ensuring that environmental and health care costs are taken into account by carriers, infrastructure providers and travellers.

In some cases, particularly for airport and highway infrastructure, it may not be possible to have more than one provider. When services or infrastructure are provided under these monopoly conditions, providers might charge prices that are too high or might not provide the service that travellers want and are willing to pay for. Governments can take steps to ensure that the services provided and the prices charged to travellers are similar to what might be expected if competition did exist.

A third thrust of our principles is directed at those situations where leaving passenger transportation to operate in a business context would have unacceptable results and must, therefore, be modified to take account of an important public interest. Although "public interest" is a vague and potentially all-encompassing term, our focus is specific. We believe that government intervention is necessary in two circumstances:

- to take care of the special transportation needs of people with disabilities; and
- to help firms and travellers who would be especially disadvantaged by an abrupt introduction of market forces to adjust to a potentially dramatic change in their operating environment.

The fourth and final thrust of our principles must be to ensure that government fulfils its role in a responsible manner. An informed public is the best check on governments. We believe there is a need for political decisions on transportation to be transparent, so that taxpayers and travellers can make informed choices. Some specific changes could help:

- Decentralization may contribute by providing those affected by government decisions with an increased say in those decisions.
- Those making decisions could be more effectively held accountable if taxpayers and travellers better understood the implications of decisions.

Our principles must impose greater responsibility for achieving our objectives on all the participants in the intercity passenger transportation system — travellers, carriers, providers of infrastructure, governments and their agencies.

These objectives will be best achieved if the passenger transportation system is supported and maintained by those who use it. Travellers should pay for the travel services they use. People who do not travel should not have to pay for those who do.

Therefore, we **recommend** that:

---

**4.3 Each traveller pay the full cost of his or her travel, and travellers, in total, pay the full cost of the passenger transportation system, including those costs related to protecting the environment, safety and accidents.**

---

We recognize that some Canadians may not be able to pay for the transportation they require. In general, when people need financial assistance to travel, this help should be provided to them through general or specific assistance programs, not by charging other users of the passenger transportation system.

In some cases, such assistance may still not make transportation services available to all. For example, although some people with disabilities could receive financial assistance to pay for travel, they may still lack physical access to passenger transportation services and infrastructure. Carriers and providers of terminals have a responsibility to provide accessible passenger transportation and should have a caring attitude toward people with disabilities.

Therefore, we **recommend** that:

---

**4.4 Travellers with physical or mental disabilities have opportunities similar to those enjoyed by all Canadians to use public passenger transportation.**

---

## PRINCIPLES FOR CARRIERS

We believe that passenger transportation carriers should provide services in a competitive environment, operating under the same commercial principles, economic forces and general rules as most other businesses in the Canadian economy. They may, however, also be subject to government rules designed for transportation, such as those associated with safety or environmental protection. As long as these carriers are charged appropriately for safety, accident and environmental costs, competition in the marketplace should be relied upon to determine the most efficient pricing and investment decisions.

Therefore, we **recommend** that:

---

**4.5 Competition and market forces be the prime agents in providing viable and efficient carrier services:**

**(a) anyone "fit, willing and able" to supply passenger carrier services have an opportunity to do so;**

**(b) carriers (including private car and private airplane owners) pay their share of the full cost of the terminals, links and traffic control services that they use, as well as any costs related to environmental damage, safety and accidents;**

**(c) as long as they are willing to pay their share of the costs, carriers have equal access to terminals, links and traffic control services; and**

**(d) anyone providing carrier services be able to withdraw these services, without undue delay, but with adequate notice to the public.**

---

## PRINCIPLES FOR PROVIDERS OF TERMINALS, LINKS AND TRAFFIC CONTROL

Terminals such as airports, links such as roads or railway tracks, and related services such as traffic control are essential for getting travellers to where they want to go. Carriers and travellers told us that if they are going to be asked to pay the full cost for these terminals, links and traffic control services, they want to be sure that what is provided is only what is needed, no more, no less. We agree.

Therefore, we **recommend** that:

**4.6 Terminals, links and traffic control services be priced on a terminal-by-terminal, link-by-link and service-by-service basis.**

We recognize that prices could also be determined by averaging across a number of links or facilities, and that, in the short term, this type of pricing may be the most feasible approach in cases such as roads.

In some circumstances, prices can be determined through market forces, as happens when one airport faces competition from a nearby airport, or when a user of a facility is in a strong bargaining position with the provider of the facility, such as a dominant airline's relationship with some airports.

Therefore, we **recommend** that:

**4.7 Where there is sufficient competition, or where users are in a strong bargaining position with providers of terminals, links or traffic control services — and so long as there are appropriate charges for environmental damage, safety and accidents — competition and market forces be relied upon to determine prices and investment decisions for passenger transportation infrastructure.**

Where terminals, links and traffic control services are provided on a monopoly or near-monopoly basis, market forces cannot be relied upon to determine prices. Monopolists can charge prices above costs and normal profits, or inflate costs by over-building. Where competitive forces are not sufficient, or where users are in a weak bargaining position, governments, as referees, must regulate prices and investment decisions on an intermodal basis.

Therefore, we **recommend** that:

---

**4.8 Where regulations are required, they be designed to ensure that pricing and investment decisions be similar to what would otherwise occur through competitive market forces. Specifically, we recommend that:**

**(a) prices reflect the traveller's or carrier's use of each terminal, link or traffic control service and be designed to encourage neither over-use nor under-use. Where such prices do not recover the full cost, we recommend that they be adjusted to provide for full cost-recovery in such a way as to minimize the loss of efficiency; and**

**(b) investments be made only in those projects where benefits to travellers exceed costs and that yield the highest level of benefits over costs, regardless of mode. In making investment decisions, all costs, including safety, accident and environmental costs, as well as interest on funds invested, should be taken into account; adequate provisions should be made for maintenance; new technologies should be considered along with existing technologies; and full consideration should be given to the potential for intermodal operations to contribute to efficiency and ease of travel.**

---

# IMPLICATIONS FOR GOVERNMENTS

## FUNCTIONS OF GOVERNMENT

We have said that competition and market forces should be the prime agents in developing a viable and efficient passenger transportation system. There are some functions in the passenger transportation system, however, that can only, and should only, be performed by governments.

Governments should be responsible for:

- establishing policies in relation to the framework — setting policy with respect to transportation agencies, establishing guidelines for project evaluations, notably for the assignment of joint costs to modes and user classes, taking a cross-modal view of transportation issues and coordinating the development of environmental and safety policies with respect to transportation;
- standards setting and enforcement — imposing safety and environmental standards, and applying charges to reflect the costs of environmental damage;
- data gathering and reporting — setting reporting requirements, and presenting data in a way that allows ready comparison by users among the various modes of transportation;
- research — together with providers of services, governments finance and carry out selected research on passenger transportation (the results of much passenger transportation research cannot be patented or sold but are of public benefit);
- maintaining competition — ensuring that carriers do not engage in anti-competitive behaviour (for example, by guaranteeing equal rights of access by carriers to terminals, links or traffic control in cases where failure to provide access could restrict competition, especially where carriers own the terminals or links, such as railway tracks or bus terminals); and
- regulating monopolies — regulating pricing and investment decisions of terminals and links that are provided on a monopoly or near-monopoly basis.

Therefore, we **recommend** that:

**4.9 Governments be responsible for establishing policies in relation to the framework, setting and enforcing standards, gathering and reporting information to the public, ensuring a sufficient level of research, maintaining competition and regulating monopolies.**

## ASSIGNING RESPONSIBILITY TO LEVELS OF GOVERNMENT

We believe that assigning responsibility to the level of government closest to the people is consistent with our objectives, since our approach does not require that transportation responsibilities be assigned to particular levels of government — whether federal, provincial, territorial, regional or municipal.

In some cases, benefits or costs may extend beyond the boundaries of one jurisdiction. Only a higher level of government, or governments acting jointly, may be able to ensure consistency. At a minimum, cooperation among the different levels of government that have responsibilities for establishing the framework, making the rules, and refereeing would be required.

In other cases, the delegation of powers or jurisdictional modifications might be required. If formal constitutional change is needed to meet our objectives, then governments should consider implementing such change.

Therefore, we **recommend** that:

**4.10 Decision making authority of governments be assigned to the level of government that is both closest to the people and most able to efficiently exercise such authority.**

## EQUAL TREATMENT OF MODES

When governments collect taxes for general revenue purposes — a general sales tax as opposed to charges to travellers — they should tax all modes of transportation on the same basis.

When governments impose charges to pay for infrastructure and services that are government-owned, the charges should reflect the efficient cost of providing the infrastructure or a service, and the revenue from the charges should be used for that purpose.

Governments should levy charges to cover any other costs that transportation activities impose on society, whether the activities arise from operations of a publicly or privately owned carrier, facility or service. Where regulations are used in place of charges, they should impose similar obligations on each mode.

Therefore, we **recommend** that:

**4.11 Governments tax and regulate all modes equally.**

## ACCOUNTABILITY

Those responsible for making and applying the rules and for spending taxpayers' money should be accountable for their actions to these same taxpayers. Governments should improve such accountability through transparency — making relevant information available and understandable.

When governments consider providing taxpayer subsidies, such subsidies should be openly debated and visible. Full disclosure of the costs of the system — revenues, subsidies, who pays and who benefits — will help people to make their own transportation decisions and to judge those made by governments. Disclosure will also provide a mechanism that enables the public to hold government agencies accountable.

Therefore, we **recommend** that:

---

**4.12 Decision making be transparent so that Canadians understand why governments or their agencies make the passenger transportation choices they make, and so that those making decisions can be held accountable.**

---

## TRANSITION MECHANISMS

We recognize that today's passenger transportation system is a long way from embodying the objectives and principles outlined in this chapter, and that such a passenger transportation system could not be achieved at once.

Immediate action to implement the new objectives and principles could lead to sharp price increases that travellers would consider unreasonable, or could jeopardize the viability of a carrier or a particular carrier service, terminal or link. Time may be needed to allow prices to adjust, and to permit current service levels to be reduced, or otherwise modified, to match demand at an unsubsidized price. Governments will also need time to assess environmental and social costs. Any transition assistance should be subject to strict guidelines.

Therefore, we **recommend** that:

---

**4.13 In cases where time is required to ease the problems caused by steep price adjustments, or where a carrier, a particular carrier service, a terminal or a link is given another chance to survive within the new framework, financial assistance be designed to encourage adjustment. Such assistance should be:**

**(a) given, where possible, to move people in the most efficient way, regardless of mode;**

**(b) provided and managed by the level of government responsible for the mode;**

**(c) borne by general taxpayers in the jurisdiction that makes the decision, not by other transportation users; and**

**(d) provided on a declining basis, for a predetermined, reasonable adjustment period, and then terminated.**

---

**4.14 If a carrier, a particular carrier service, a terminal or a link cannot survive despite a reasonable period of time for adjustment, the terminal or link be closed or the service discontinued.**

---

Carriers and providers of terminals, links and traffic control services should be given maximum flexibility from regulation in order to adjust fares and the frequency and quality of service. This flexibility should also permit substituting services that use another mode of transportation.

## CONCLUSION

Establishing the foundations for a new framework and the transition mechanisms required to achieve them are only first steps toward solving transportation problems. We must emphasize that these first steps are essential if Canadians are to make the right decisions in the future.

In the following chapters, we apply our approach to a range of issues in intercity passenger transportation.

# ENDNOTES

1. The test of "demand" should be the price that travellers are prepared to pay and the test of "supply" should be the amount that would be provided in a competitive market, when all costs are taken into account.

2. If, for example, governments decide that it is desirable to encourage students to travel around Canada by subsidizing 20 percent of their fare, this could be accommodated by the transportation system but we do not view it as a transportation policy. The cost should be ascertained and the full cost should be paid to the passenger transportation system by all taxpayers. The passenger transportation system and its travellers should not have to shoulder the burden for a nation-building policy that governments feel benefits all Canadians.

# CHAPTER 5

# TRANSPORTATION INFRASTRUCTURE: INVESTMENT AND PRICING

## INTRODUCTION

One of our objectives for the national passenger transportation system is fairness to users, carriers and the general taxpayer. We believe that fairness cannot be achieved if the current system of payment for government-provided transportation infrastructure remains in place. This system gives some modes a competitive advantage over others, and often means that the general taxpayer, who may not travel often or at all, pays for Canadians who do. As we stated in Chapter 4, our principles are that:

- each traveller pay the full cost of his or her travel, and travellers, in total, pay the full cost of the passenger transportation system, including those costs related to protecting the environment, safety and accidents (Recommendation 4.3);
- carriers (including private car and private airplane owners) pay their share of the full cost of the terminals, links and traffic control services that they use, as well as any costs related to environmental damage, safety and accidents (Recommendation 4.5b); and
- as long as they are willing to pay their share of the costs, carriers have equal access to terminals, links and traffic control services (Recommendation 4.5c).

We also believe that pricing to cover full costs, when applied intelligently, can offer major benefits in addition to fairness among different groups of users and between users and general taxpayers. Pricing can:

- help ensure that existing infrastructure is used in a way that offers the greatest economic benefit to Canada;

- provide valuable guidance for new investment decisions; and
- provide a basis for decentralizing the operation and management of infrastructure. In the absence of prices for outputs and inputs, it is difficult to give local management the power to decide how many and which services to offer, and which combination of resources to use in the production of services. Decentralization provides greater flexibility to meet local needs and can encourage managers to achieve the lowest cost for operations.

We emphasize that our approach to pricing is not designed to provide infrastructure providers with a means of passing any and all costs on to users. Rather, our approach is designed to ensure that costs are subject to greater discipline and that operating efficiency is increased.

We also want to reiterate that the costs we are discussing are already being paid. They are not new costs. Our concern is that the taxpayer, who may or may not travel, not be saddled with expenses that benefit those who do travel. While our framework will raise the cost to the traveller, we expect that it will lower the burden on the taxpayer.

In this chapter, we explore the costs of transportation infrastructure, how investment decisions should be made to ensure that the appropriate amount of infrastructure is in place, and methods for setting charges. In Chapter 6, we discuss access to infrastructure and the institutional arrangements for its ownership and management.

## TRANSPORTATION INFRASTRUCTURE: AN OVERVIEW

### COMPONENTS OF THE TRANSPORTATION SYSTEM

As we noted in Chapter 2, transportation infrastructure refers to the non-carrier component of the intercity transportation system: terminals, links, and traffic control systems (Table 5-1).

*Table 5-1*

*COMPONENTS OF THE TRANSPORTATION SYSTEM*

| **Mode** | **Carrier** | **Infrastructure** | | |
|---|---|---|---|---|
| | | **Terminals** | **Links** | **Traffic control** |
| **Road** | Cars | Car parking | Roads (including bridges) | Police, road signs and signals, traffic control laws and regulations |
| | Buses | Bus terminals | | |
| **Air** | Airplanes | Airports (including runways) | Air navigation systems | Air traffic control |
| **Rail** | Trains | Stations | Railway tracks | Dispatch, signal systems |
| **Water** | Ferries | Ferry terminals (including wharves and ferry slips) | Waterways and canals (including navigational aids) | Vessel traffic services |

Today, the federal, provincial and territorial governments own and manage most of Canada's intercity transportation infrastructure. The federal government supplies airports, air navigation and air traffic control, and services for water links. Provincial and territorial governments design, build and manage roads and highways. Some carriers own and manage rail tracks and terminals, most bus terminals and some ferry terminals.

## CAPITAL AND OPERATING COSTS

System-wide cost estimates for passenger transportation (Table 3-1, Chapter 3) show that the capital and operating costs of transportation infrastructure are $6 billion per year or, on average, 14 percent of the total cost of intercity travel. This estimate includes an "interest charge,"[1] as well as depreciation on the existing physical capital. Our estimates, however, are only approximate. Governments, which build and own most infrastructure, rarely keep records that show the value of the infrastructure. Our estimates are intended to reflect current replacement costs.

In most cases, intercity travellers share passenger transportation infrastructure with other users. For example, freight and passenger motor vehicles, as well as urban and intercity travellers, use the same roads. It is often difficult to allocate infrastructure costs accurately among the different users. In our calculations, we have allocated the following percentages of infrastructure costs to intercity passenger transportation:

- 70 percent of the intercity road network to passenger vehicles;
- 84 percent of airports and the air navigation system to commercial passenger aircraft;[2]
- 2 percent of the rail network to passenger rail; and
- 12 percent of selected government expenditures for marine links and control systems (primarily aids to navigation and coast guard services) to passenger travel on ferries.

## MAKING INVESTMENTS IN TRANSPORTATION INFRASTRUCTURE

### PRIVATE-SECTOR INVESTMENT DECISIONS

Private-sector companies base their transportation infrastructure investment decisions on expected profitability and a return on their investment. We believe this criterion is appropriate as long as these firms are not making monopoly profits that distort their decisions, and are taking all costs into account, including those related to environmental damage, safety and accidents.

### GOVERNMENT INVESTMENT DECISIONS

In the past, governments have often used transportation as a tool of public policy, making investment decisions that served political, economic and social goals in addition to transportation goals. We believe such goals are inappropriate for the passenger transportation system of the future. Today's passenger transportation system is now mature, and Canadians in most of the country are served by several modes of transportation. Although there may be some areas where new investment is required for expansion, most expenditures are now made to maintain, replace, and upgrade infrastructure. We believe that infrastructure expenditures, if they are to be made by government at all, should, from now on, be made only if they are expected to provide a return on investment.

Two factors determine a return on investment: benefits and costs. While the total expected cost of an investment project is often easy to calculate, the expected benefits are much more difficult to estimate. The benefits for private-sector projects are based on expected increased revenues and cost savings from the investment. Revenues are determined by what people will pay for the new good or service and by how much of it they will purchase.

What are the benefits of a new road or an airport terminal? How can they be calculated? Under our principles, users should pay for what they use, and the price they pay should cover all costs, including those associated with environmental damage, congestion and safety measures. We believe that governments should measure benefits using the same yardstick as that of the private sector: the prices users are willing to pay and the revenues that the infrastructure is expected to generate.

## THE PRINCIPLES OF INFRASTRUCTURE PRICING

The total costs of transportation infrastructure are substantial. At the same time, adequate infrastructure is essential if efficient transportation services are to be available. Excessive infrastructure is wasteful because the resources used could have been used to produce other needed goods and services. In the case of government ownership, excessive infrastructure is thus an unnecessary burden for taxpayers. Yet too little capacity, or capacity of the wrong type or in the wrong place, is also wasteful since it causes delays in the movement of people and goods. These delays reduce the ease of travel, add to the uncertainty and costs of doing business, and thus reduce Canada's productivity and competitiveness.

## EFFICIENT PRICING

**Efficient prices = prices that lead people to travel without wasting resources or losing opportunities**

Efficient prices encourage people to use the road, rail, air and water modes in a way that does not waste resources or opportunities. These prices are also fair if users who are responsible for the same level of costs pay the same amount.

When travellers must pay for all of the costs incurred in producing transportation services, they will balance their use of these services against their costs. They will not use a facility more than they need to, because this wastes their money; nor will they use a facility less, since this wastes an opportunity.

Charges to travellers also test the public's willingness to pay for infrastructure investment. Over time, the capacity of transportation infrastructure requires expansion, contraction or change. Governments should use consistent rules to evaluate new investment projects. Charges provide a means of developing such rules by measuring Canadians' desire for expanding, changing or reducing the capacity of infrastructure or the size of transportation networks.

## MARGINAL COST

### Marginal Cost as a Starting Point

An important starting point in establishing prices for transportation infrastructure is the marginal cost — the additional cost that occurs when there is an increase in the amount used of a product or service, such as a road or a runway.

**Marginal cost = the additional cost that results from a small increase in the amount provided of a product or service**

**Example of a marginal cost: the cost for the wear imposed on a road every time a vehicle uses the road**

For example, the marginal cost of a road is the cost of the wear on the road incurred each time a vehicle uses the road. If operators of vehicles do not pay for the damage they inflict to the road, they have no incentive to reduce vehicle use or to switch to less-damaging vehicles. Generally, when users do not fully pay for the marginal costs of infrastructure — that is, when they face a lower charge than the costs they impose — their transportation choices cost the economy more than the return or value they receive. In our example, if users do not pay for damage to roads, they may choose to make an unnecessary trip, or use a vehicle that is cheaper to operate but causes more road wear. The benefits of such trips to the user are small, but the costs to the taxpayer may be substantial.

### Operational Limitations in Applying Marginal-Cost Pricing

For many types of transportation infrastructure, as in other public utilities such as electrical power and telephone services, marginal costs are difficult to estimate or apply. There are four reasons for this:

First of all, marginal cost may be difficult to measure. For example, analysts may not agree on the amount of damage that heavy trucks impose on different types of roads.

Secondly, marginal cost may vary with circumstances. For example, the amount of damage trucks cause to roads may increase during spring thaw. Or, the cost of handling additional passengers in a terminal may increase if the terminal is already at the normal level of use and extra staff have to be hired. If these variations in cost are predictable, it may be possible to vary prices to match the variation in cost — although changing prices may involve added complexity for the operator of the facility, and for users. Not all such variations in costs, however, are predictable, and transportation providers may not be able to set prices easily or accurately.

Thirdly, electronic technology is sometimes able to provide instantaneous information on variations in cost, and to identify the amount of use by individual users at any given moment. Although users are sometimes in a position to respond to varying prices, there are many circumstances in which fine-tuning prices to match variations in marginal costs is impossible, or not worth the inconvenience to suppliers and users. For example, it may be possible to keep track of variations over the day in the cost of producing electricity — as different cost sources of supply are used. But, for a household, as opposed to a large industrial user, it might not be worthwhile to keep watching the (hypothetical) price meter and adjusting use of electrical appliances as the price changes over the day.

Finally, even where marginal costs can be measured with some precision, infrastructure providers sometimes find it difficult to collect charges from users. Roads, especially those other than limited-access highways, are a good example of this. The main method of charging directly for road use is a type of toll booth. But toll booths, unfortunately, produce additional costs for the road owner and delays for the users. These additional costs would be especially large, relative to the costs of use of the road itself, for short trips using road systems with frequent access points and intersections. For these reasons, toll roads have been the exception rather than the rule, and — if used at all — are used only on limited-access highways. Instead, governments use fuel taxes, which can only be related approximately to the amount of road use and its costs, as the principal means of charging drivers for road use.

Developments in electronics may eventually make it possible, without great expense or invasion of privacy, to identify moving vehicles on a segment of road, and then charge for use. This might be done using an electronic card, for which credit balances could be purchased, and which was automatically debited by signalling devices in, on, or near the road.

## PRICING TO RECOVER TOTAL COSTS

### When Marginal-Cost Pricing Causes Deficits

An important further limitation in applying marginal-cost pricing is financial, rather than operational. In many cases, it costs a substantial amount to provide a basic level of infrastructure such as a two-lane highway or an airport large enough to handle certain types of aircraft. The marginal costs associated with additional users, however, may be small.

**Example of how marginal-cost pricing can result in a deficit:**

- **A facility serving 100 users costs $1,000 per day, for an average cost of $10 per user.**
- **It costs only an additional $5 to provide service to each user after the first 100 users.**
- **If there are 200 users a day, the total cost is $1,000 for the first 100 users and $500 for the additional 100 users. The total is $1,500, or an average cost of $7.50 per user.**
- **If the price for all users is set at the marginal cost — $5 — revenue would be only $1,000, resulting in a deficit of $500.**

Transportation infrastructure pricing involves a difficult choice when marginal cost is less than average cost, a situation that can arise when producing the service requires an expensive basic facility whose capacity can be expanded cheaply. To charge more than marginal cost is not efficient because some potential users, who would have been willing to pay the marginal cost and who would have gained from using the facility, would not do so at the higher price. This non-use means a loss to the economy. And yet setting the price equal to marginal cost means a financial deficit in operating the facility.

If a government decided to set prices equal to marginal costs, and to accept the financial deficit, general taxpayers would then be financing the deficit and would in effect be paying for a part of the provision of benefits to users. The results of this are:

- a transportation system that violates our principle of fairness to taxpayers, users and carriers;
- a need for higher general taxes, which causes distortions in price-cost relationships elsewhere in the economy that will, in turn, cause losses of benefits to the economy; and
- pressures for government intervention into the management of that infrastructure requiring subsidies. Such intervention may reduce the pressures for cost efficiency that would occur if the infrastructure was run on a more commercial basis.

As well, in making investment decisions to add or close infrastructure, it is necessary to test how much users value the basic infrastructure, not just how much they value additional amounts of service or use. Marginal-cost pricing does not provide a complete test.

On balance, we favour a policy under which users pay the full cost of the infrastructure they use, assuming that such costs are no higher than necessary. In many cases, this policy of full cost recovery may require prices to be set above marginal cost.

### Pricing to Avoid Deficits

There are several ways of pricing that enable infrastructure owners to achieve full cost recovery:

*Setting prices equal to average costs:* This approach is not as simple as it appears. There may be different categories of users, such as vehicles that take up different amounts of space and/or have different weights. The average cost could be calculated by the total cost divided by number of vehicles, by total square metres occupied by all vehicles, or by total weight of all vehicles. Each calculation would result in different charges for each category of vehicle, and thus in a different pattern of use.

*Determining responsibility for costs:* Careful consideration of costs associated with different types of users may provide a better basis for allocating total costs than some simple average. For example, if heavier or larger vehicles require a road or runway to be built to a higher standard, the extra costs of building to the higher standard can be assigned to heavy vehicles when setting prices. If more capacity is needed to serve users at peak periods, these users can be charged an additional amount to cover the extra cost.

*Pricing according to benefits:* Prices incorporating costs that can be directly attributed to particular groups of users may still not cover total costs. One could set prices in a way that least reduces the use of the infrastructure and thus minimizes the economic loss associated with a reduction of use. If this were done, the benefits obtained by various users, as well as the costs for which they are responsible, would determine the price.

One option is to use a mark-up over marginal cost that varies with the extent of benefit. The benefit could, in principle, be measured by how much the use of the facility by a group of users declines as the price increases. The smaller the decline, the more the group appears to value the benefit of use. This option is related to the practice known as "value of service pricing" or "charging what the market will bear." Railway companies, whose average costs are generally higher than their marginal costs, traditionally use this type of pricing when setting freight rates for different categories of products.

Our principles do not support unconstrained charging of what the market will bear. Rather, we intend that infrastructure providers charge a sufficient amount to cover full but efficient costs.

*Two-part pricing:* With this approach, infrastructure providers charge one amount for the right to use a facility — such as an annual fee — and a second charge on a per-use basis. This system is found at some golf courses that charge an annual membership fee as well as "green fees" for every round of golf played. A transportation example of two-part pricing is the annual car licence fee, coupled with a fuel tax that varies according to use. The per-use fee can be set at, or moderately above, marginal cost, and the annual fee can be used to cover the gap between total cost and revenues generated by the per-use charges. The annual fee may also differ across classes of users, depending on the benefits that each group derives from the infrastructure.

**Recommendations for Pricing**

As part of Recommendation 4.8 (Chapter 4), we propose that prices be set to encourage neither over-use nor under-use of transportation infrastructure. In addition, we suggest that where such prices do not recover full costs, they be adjusted to cover this cost so as to minimize the loss of efficiency. In this chapter, we have argued that setting prices equal to marginal costs encourages the appropriate amount of use of a facility. We have also discussed the general options available to achieve full cost recovery where setting prices equal to marginal costs would not cover total costs.

We realize that infrastructure owners will be required to make shrewd assessments when selecting appropriate prices for individual facilities. They will have to decide how far to go in developing finely tuned prices by balancing the benefits of more accurate incentives against the costs of greater complexity in compliance and administration. Those who wish to raise prices above marginal-cost prices must assess which pricing approach will least discourage use. At the same time, they must decide on the fairness of imposing different prices on various groups of users. We believe that marginal cost should be the starting point to guide transportation infrastructure pricing policy. Where required to achieve full cost-recovery, mark-ups over marginal cost and/or entry fees should be set, taking account of benefits to different classes of users.

## PRICING NETWORKS

Two types of transportation infrastructure — links and terminals — can be grouped into networks. For example, the road links in the Trans-Canada Highway make up a network, as do the road links in the non-urban road system of a province or territory, the route links in the air navigation system, or a group of airports used by commercial air carriers.

When owners provide a network of links or terminals, they tend to apply a common pricing formula to the entire network or major portions of it, rather than set individual prices based on the costs and demands associated with each link or terminal. For example, motor fuel taxes, which we view as the main charge for the road network, have a common basis within a province. For a given type of vehicle, the effective charge is almost constant per kilometre travelled, and does not vary with the cost of, or demand for, the section of road being used. Another example is the Air Transportation Tax, which is the primary charge for the air navigation system. It is not closely related to costs of, or demand for, the air navigation services provided on particular flights since it is a charge on each passenger and results in higher charges for larger airplanes.

### The Stand-Alone Approach

Under our principles, travellers and carriers should pay the cost of the infrastructure they use. Should this coverage of costs apply to the network as a whole, or to as small a segment of the network as is practical?

In Chapter 4, we stated our preference for the stand-alone approach — users pay link by link or terminal by terminal.

The stand-alone approach is consistent with the principle that individual travellers and carriers pay the costs of infrastructure provided for their use. It also eliminates cross subsidies from one link or terminal to another, either within a mode or between modes.

Individualized pricing tests users' willingness to pay, and provides valuable information for decision makers who are considering the addition, expansion, or abandonment of links or terminals. If prices are set on a network-average basis, potential users of a proposed high-cost link or terminal may want its construction even though its benefits would not be worth its full costs. They know that such an addition will have a minimal impact on the network's average cost, which is all they will have to pay.

Prices related more closely to actual costs send the right economic signals to travellers in their choices of route. For example, the wear imposed by heavy trucks on roads is substantially less on main highways that are built to higher standards than it is on secondary roads. If a standard charge per kilometre for a given type of vehicle is applied, equal to the average cost of wear by that type of vehicle over the whole network, the charge will be greater than the actual cost of wear on main highways and less than the actual cost of wear on the secondary roads. The failure to relate charges to actual costs will tend to lead truck operators to choose routes that are inefficient to the economy when all costs are taken into account.

Setting average prices over networks consisting of high- and low-cost routes can also lead travellers to a choice of modes that is not beneficial to the economy. If such prices are different from route costs, users on a given route may be induced to choose a mode that has higher costs to the economy for that route.

The arguments in the preceding two paragraphs are subject to exceptions. These arguments are based on prices being better aligned to marginal cost under the stand-alone approach. However, given the frequent need for a mark-up over marginal costs to cover full costs, and the fact that the required mark-up may vary from link to link or terminal to terminal, prices under a stand-alone system may not always be closer to marginal costs for the different units than under a network-average pricing system.

Current practices in individualized pricing, and the practicality of moving toward such pricing, differ substantially across the modes and the various facilities that they use. For example, bus terminals are effectively priced on an individual basis, while a user of the road system generally pays an almost constant charge per kilometre for a given vehicle anywhere within a province.

In the following sections, we apply our general pricing principles to the terminals, links and control components in the different modes and discuss how far and how fast the stand-alone approach might be implemented. We do not illustrate potential charge levels. We discuss charges for environmental and accident costs in Chapters 7 and 8 and draw overall conclusions in Chapter 18 as to the set of charges that users of a mode might pay.

## APPLYING THE PRINCIPLES TO TERMINALS

### BUS TERMINALS

Current pricing for bus terminals is close to the stand-alone approach that we recommend. In many cases, intercity bus companies own the terminals and face the full cost of providing services. Where municipalities own terminals, the terms that individual carriers negotiate likely reflect some combination of the costs of using a terminal and the benefits of that use to the carrier.

Bus terminals vary in size and, in a few cases, are integrated with terminals for other modes of intercity transportation. For example, the terminal can be a simple passenger pick-up and drop-off point next to a rural gas station or urban hotel. In other cases, central bus terminals in major cities provide passengers with a substantial range of supplementary services ranging from restaurants to newsstands.

Under our principles, there should be open access to essential infrastructure for all carriers prepared to pay for their cost. We believe that in most locations potential operators have sufficient options to obtain space in, or to create new, terminal facilities. We are not concerned about monopoly power in such situations. In cases where access to a single terminal is of critical importance, however, a referee may be desirable, especially where the terminal is also owned by a major carrier. Federal legislation and policy on competition provide some protection of access rights for competitors when a major carrier owns a terminal, but such rights may require reinforcement.

## RAIL STATIONS AND FERRY TERMINALS

Rail stations and ferry terminals, which are also frequently owned by carriers, do not raise any issues additional to those we have addressed concerning bus terminals.

## AIRPORTS

### Current Pricing

Transport Canada owns and operates the majority of Canadian airports serving scheduled air carriers. The primary charges are landing fees set according to a schedule that varies little from airport to airport. The federal government has also allocated a share of revenue from the Air Transportation Tax to cover the costs of the entire airport network. Revenues from concessions at airports also cover some airport costs.

The recent federal initiative to lease Transport Canada airports in Vancouver, Calgary, Edmonton and Montreal to newly created Local Airport Authorities (LAAs) should help move airport pricing in a direction that is more consistent with our pricing principles. The LAA airports will, after a brief transition period, have to recover full costs from users, including operators of concessions. The LAAs will not receive any share of the Air Transportation Tax and will set landing fees and possibly passenger facility charges according to their individual requirements.

Once an airport terminal is built, marginal costs for use by an additional aircraft with passengers are often low. Therefore, charges should also include some amount for the value of the service provided to the passenger. Aircraft weight may be a reasonable indicator of this value.

At airports, the demand at peak periods can strain capacity and may lead to expensive investments for expansion. In such cases, higher prices for peak-period users — aircraft and/or passengers — could encourage the highest-value use of the existing infrastructure and provide a test of the value that users attach to expansion investment.

### Applying the Stand-Alone Approach

To find out how charges would vary by type of airports, if all airports operated on a stand-alone, full cost-recovery basis, we obtained estimates of the full costs attributable to commercial aviation at 98 airports owned by Transport Canada, as well as the current revenues obtained from landing fees and terminal charges. Table 5-2 presents these estimates for five categories of airports:

I. Vancouver and Toronto (which are the two largest airports and the ones currently closest to full cost-recovery).

II. The next six largest airports (in passenger capacity).

III. The next 20 airports (in passenger capacity). These airports were designed to handle more than 200,000 passengers per year.

IV. Twenty-six airports (generally serving smaller cities and towns, but oriented to scheduled commercial aircraft).

V. The remaining airports that also serve smaller cities and towns. (These airports are often in northern areas; some are not oriented primarily to commercial aviation. The estimated costs per commercial passenger for this group are less reliable.)

*Table 5-2*
*Summary of Airport Cost Recovery, 1988*

| **Airport category** | **Number of airports** | **1988 Enplaned/ deplaned passengers (millions)** | **Cost attributable to commercial aviation (airlines)[a]** | | | **Full cost[c] less revenue from commercial aviation per passenger[a] ($)** |
|---|---|---|---|---|---|---|
| | | | **Full costs[b] ($ millions)** | **Operating costs per passenger ($)** | **Full cost per passenger[b] ($)** | |
| I. | 2 | 29.1 | 310 | 2 | 11 | 6 |
| II. | 6 | 22.9 | 350 | 3 | 15 | 10 |
| III. | 20 | 7.4 | 160 | 9 | 21 | 18 |
| IV. | 26 | 2.2 | 100 | 18 | 46 | 44 |
| V. | 44 | 1.2 | 180 | 51 | 146 | 140 |
| **Total** | **98** | **62.8** | **1,100** | **5** | **18** | **13** |

**a. 1988 cost and revenue estimates are in 1990 dollars.**

**b. For categories I, II and III, full costs include an approximate allowance for land costs of $5 per passenger. See Notes to Chapter 3 in Volume 2.**

**c. Full cost per passenger from previous column.**

We first discuss the airports in categories I to IV, given the special circumstances of many airports in Category V.

If charges were set to fully recover costs in the first four categories of airports, there would be an appreciable increase in the cost of air travel for users of the airports in Category III and especially Category IV. Under full recovery of present levels of costs, charges per passenger, on average, would increase by the amount shown in the final column in Table 5-2. These charges, however, would not necessarily be applied directly to passengers as a uniform per-passenger charge equal to the average amount shown. Some of these costs would be incorporated in landing fees charged to the carrier and/or in terminal fees charged to carriers or passengers. Charges may be direct to the airline but are then reflected in the traveller's ticket price. It should be noted as well that, from the traveller's point of view, the overall increase in prices would be offset to some extent by eliminating the portion of the Air Transportation Tax currently assigned to airport funding.

The federal government, however, did not build these airports with the intent of full cost recovery, and the airports are run under a centralized system that does not pressure management to find innovative ways of achieving cost savings and of increasing revenues. If management operated airports with greater efficiency and lowered operating costs, the increase in average charges would not be as large as the amounts shown.

We note, for example, that Oshawa Airport, which is not federally operated but is locally run, handles about the same number of passengers as the smaller airports in Category IV and covers its operating costs with charges to travellers.[3] Although there are many important differences[4] between the two airports, a comparison between Oshawa and the Transport Canada-operated airport at Yarmouth is interesting (Table 5-3).

*Table 5-3*
*COMPARISON OF YARMOUTH AND OSHAWA AIRPORTS, 1987*

| | **Yarmouth** | **Oshawa** |
|---|---|---|
| **Annual operating deficit ($)** | 700,000 | 0 |
| **Operating hours (per day)** | 9 | 16 |
| **Total movements (per year)** | 10,000 | 98,000 |
| **E/D[a] passengers (per year)** | 35,000 | 38,000 |
| **Staff** | 20 | 3 |

**Source: See endnote 3.**

**a. Enplaned, deplaned passengers.**

The airports in Category IV, on average, cover only 14 percent of operating costs with charges to travellers. We believe that if these airports were run locally, had to meet costs through charges to travellers, and were not subject to central policy requirements more appropriate for larger airports, they could eventually reduce operating costs substantially. The result would be terminals that are less expensive and better matched to the level of services required by the community.

### Recommendations for Airport Pricing and Investment

Investments, such as new runways at airports, should be made according to our principles. The federal government is proceeding with the necessary studies in order to build three new runways at Lester B. Pearson International Airport and two at Vancouver International Airport. The full costs of these projects, including interest charges, should be recovered from the users of these airports. Even though the federal government has progressed beyond the point of initial consideration, it nevertheless should apply our principles to these major investments.

We **recommend** that:

---

**5.1 (a) Airport pricing and investment be on an airport-by-airport basis; and**

**(b) The Air Transportation Tax not be used to help fund airports.**

---

We recommended in Chapter 4 that government provide financial assistance, on a declining basis, to ease adjustment in situations where applying our principles would result in steep price increases.

Therefore, we **recommend** that:

---

**5.2 Where applying our principles to airports, including all Transport Canada airports, would result in steep increases in average charges to travellers, governments provide transitional assistance:**

**(a) at an initial level based on the current subsidy of operating costs;**

**(b) to be phased out over 10 years;**

**(c) to be used for capital as well as operating expenditures; and**

**(d) if the airport is closed, to be used locally for other transportation purposes.**

---

As we noted, governments built some airports on a larger scale and to a higher standard than was necessary, and with the expectation that taxpayers and not travellers would pay for the costs. In commercial terms, it makes no sense to try to recover the full capital costs of such existing airports. A write-down in value is necessary, and Transport Canada's charges to the airport authority for capital costs should reflect this write-down. If the federal government decides to turn such an airport over to a local authority, it may in some cases be appropriate to transfer it without charge. Any new investment, however, should not be made unless the prices to be charged can be set in such a way as to provide a positive return on the investment.

We therefore **recommend** that:

---

**5.3 (a) The valuation of existing airport capital facilities used for establishing charges to travellers, and for transferring the airport to local airport authorities, reflect the commercial potential of the airport, not historical costs; and**

**(b) New investments be made in an airport only when costs, including a return on the investment, are expected to be repaid through future revenues.**

---

According to our estimates, airports in Category V have extraordinarily high costs per passenger. Passing on such costs to travellers would cause a sharp curtailment in use. While it is possible to run many of these airports in a more cost-efficient manner, especially if requirements more appropriate for larger airports are removed, we realize that several airports may have no prospect of survival on a stand-alone commercial basis.

Governments may wish to retain some of these airports for reasons of national defence, health services, emergency evacuation, or other purposes not related directly to providing passenger transportation. In such cases, governments should support the airport with general taxpayer-financing and indicate clearly the purpose of the airport and the financing of it. Airport management should also allow commercial aircraft to use the terminal when this is compatible with the purpose of the airport. Charges for such services should include the cost of any extra facilities provided and should not be less than the levels of charges at small but financially self-sustaining airports.

Where governments judge that there is insufficient reason, on grounds other than commercial transportation, for keeping the airport open, they should apply the general transition mechanism that we suggested for other airports — a subsidy sufficient to avoid sharp initial increases in charges, but phased out over 10 years. Governments should not undertake any new capital spending that cannot be recovered from future revenues. The terms of transfer of the airport to a local operator should reflect the airport's commercial value, which may be well below its historical cost. At some stage in the transition, it may become clear that an airport is not viable and should be closed.

## APPLYING THE PRINCIPLES TO LINKS

### THE ROAD NETWORK

Until the beginning of the 20th century, roads were a necessary, but secondary, means of transportation compared with rail and water. The advent of the automobile and truck caused this form of infrastructure to come to dominate our transportation system and restructure Canadian lifestyles. One significant change was in the method of funding roads. While there was a mix of public and private infrastructure before 1900, after that date, nearly all roads outside of dedicated logging and mining infrastructure were provided by local and provincial governments. Most of the developing system was also provided free of direct charges, and today there are only three toll bridges and one toll road in the entire country. (Including international toll bridges and tunnels in the count would boost the number.)

Since the 1920s, although some of the cost of roads has been offset by fuel taxes and by specific property assessments for municipal upgrading, the road system has essentially been built by government departments financed through general taxation. This situation has begun to change because technology has made it possible to levy charges directly against users. Charges or taxes on fuel consumption in Canada are now partway between those in the United States (low) and Europe (high), and go a substantial way toward offsetting the cost of today's system. Electronic road pricing[5] is technologically feasible, and we believe it will be introduced in some countries in the next two decades. In the United States and other countries, examples exist of automatic toll facilities, reading electronic toll tags.[6] The move from general revenue-based subsidies to a pay-as-you-go system of road pricing is possible now, and some move to link-by-link pricing is feasible in the near future.

### Fuel Taxes and Licence Charges

We realize that applying our pricing principles to road links will be gradual. Our cost analysis also suggests that a large increase in charges is necessary if users are to pay for the road system. Initially, the shift to a pay-as-you-go system should be achieved through increases in the existing fuel taxes and licence charges, which are generally set on a province-by-province basis. Governments should identify and set aside the infrastructure component of these charges (Chapter 6). We do not want higher fuel taxes and licence fees to be added to the existing tax structure and thus form additional, windfall revenue for governments. We strongly believe that increases in fuel taxes and licence charges should be offset by reductions in the general taxes that currently pay for most road costs.

Canadians, as travellers and as taxpayers, are already paying for total road costs; we are advocating a shift from tax dollars to charges to travellers, not an increase in the total burden.

The marginal cost of road use by cars is low. Marginal-cost pricing would not cover full costs, but using fuel charges to cover full costs, or some other basis that relates charges strictly to distance driven, would tend to discourage road use more than is necessary.

We have examined different pricing approaches that would set a fair charge for cars and still cover road costs:

- Using only fuel taxes to recover road costs would result in a substantial increase above marginal costs in the road component of fuel taxes, thus discouraging road use.
- Raising licence fees would lessen the increase required in the road component of fuel taxes and might discourage road use less.

- Licence fees might also be set according to the value of benefits received — for example, higher licence fees would be charged for heavier and/or higher-priced cars if authorities judged there to be an association between the price of the car and the owner's valuation of the opportunity to use the roads. Any such approach would inevitably have to be based on use of a rough indicator — such as car weight or car price — of the value of benefits received.

When road owners set road charges to travellers, they must also include charges for environmental and accident costs. The current system of charging for accident costs involves an annual insurance premium that varies little, if at all, with annual distance driven. The result is that, for each additional kilometre that road users drive, they face less than the marginal costs of the accidents they impose. As noted earlier, however, using the fuel tax as the main road charge for cars is almost certain to cost travellers substantially more than marginal road-use costs. Therefore, the low marginal charges for accident costs would tend to offset the excess marginal road charges collected through a fuel tax. This balance lessens concerns about continuing to depend on annual insurance premiums and fuel charges to efficiently allocate road capacity.

We believe that charges on fuel will be used for some time to cover a major portion of road costs. As we shall discuss in Chapter 7, fuel taxes may also be appropriate as a means of charging for environmental damage. If transportation is to pay its costs but not more than its costs, and if governments are to treat the different modes equally, there should be no special taxes on transportation that are above the taxes or charges required to meet infrastructure, environmental, safety and accident costs.

Therefore, we **recommend** that:

---

**5.4 All fuel taxes be used for transportation purposes or as a means of charging for costs caused by transportation, such as environmental damage and the health care system costs.**

---

Since the federal government provides few roads, the federal excise tax on gasoline and diesel fuels should be withdrawn except to the extent that it proves to be an appropriate environmental charge. Provincial taxes on fuel used by rail and air, for which provincial governments provide few services, should be withdrawn except to the extent that these taxes prove to be appropriate charges in environmentally sensitive regions for which provinces take responsibility (Chapter 7).

### Charges for Heavy Road Vehicles

Trucking was not specified in our mandate, but our proposal to recover road costs from users requires an appropriate division of those costs among cars, buses and trucks. Costs of road wear are generally much greater from heavy trucks than from cars, but different trucks impose different costs. Even though current provincial/territorial truck registration fees rise with truck weight, estimates prepared for the Royal Commission (Volume 2) suggest that heavy axle-weight[7] trucks currently pay less than their total cost of road wear. They may, in some cases, impose greater costs per vehicle-kilometre in terms of road wear alone than they pay in fuel taxes per vehicle-kilometre.

For heavy vehicles, we suggest adding an axle-weight and distance tax to the fuel tax to bring the total charge at least up to the marginal costs they impose. By aligning total charges more closely to the wear imposed by trucks with different weights and axle/tire configurations, the additional charge would encourage truck operators to choose vehicle types and loading practices that imposed less wear on roads. In addition, the charge would achieve more equal treatment of trucks and rail in the movement of freight, as rail freight generally covers its full costs.

Therefore, we **recommend** that:

---

**5.5 Provincial and territorial governments institute weight-distance taxes for trucks as part of an overall road-financing program.**

---

### Conventional Toll and Electronic Road Pricing

While we realize that fuel taxes, weight-distance taxes and licence fees applied provincially or territorially will constitute the major charges for road use in the future, specific link-by-link charges more fully reflect our principles and are already practical in some cases in their traditional toll form.

Therefore, we **recommend** that:

---

**5.6 Conventional tolling systems be considered when new or expanded limited-access highways are required, with tolls set to cover any costs of the road link in question that exceed those recovered by fuel taxes.**

---

In addition, governments could use tolls to levy a higher charge on peak-period users if congestion is a problem on a road. Toll roads should also provide an opportunity to test and improve electronic systems for identifying and charging for vehicle use.

### Longer-Term Directions of the System

Over the longer run, we expect that developments in electronics will make it inexpensive to identify vehicles, record locations and times of road use, and charge accordingly. We suggest that governments give serious consideration to a system in which charges per vehicle-kilometre vary by vehicle type, road used and time of use. When it becomes technically possible to apply a pricing structure of this type, the benefits of doing so should be weighed against any disadvantages (increased complexity for travellers, for example). The benefits from individualized pricing are greatest where costs, especially marginal costs, differ substantially among route links and where travellers' decisions are likely to be significantly affected by differences in price. Where cost differences are modest, a system of common rates of charge for substantial groupings of road segments and vehicles may provide the simplest solution.

The use of light vehicles on low-volume rural roads and other local access roads may generate marginal costs much lower than the average costs per vehicle-kilometre. The result is that, to cover the full costs of the road, users would have to pay high charges. We believe there is no point, once a road exists, in wasting opportunities by discouraging road use. Local property taxes, or other local taxes levied on those who receive the primary benefits from such roads, may be an appropriate source of funding for part of the costs. Governments will need to reconsider such sources of funding as the pricing of the road system moves toward a link-by-link basis.

## AIR LINKS: NAVIGATIONAL AIDS

Air links are serviced by the navigational aids used by scheduled commercial and other aircraft. Inter-airport air traffic control, especially as it evolves toward a highly automated system, can also be treated as part of air links for pricing and investment purposes.

The cost of the air navigation system involves a large capital component with almost no extra costs to add more users. Therefore, charges will have to be set above marginal costs if total costs are to be recovered. The excess of charges over marginal costs should be related to the users' valuation of their benefits. Pricing in this way would minimize the extent to which charges that recover full costs cause aircraft operators and potential operators to forego use of the facilities. Pricing based on distance flown and size of aircraft is one way of recognizing the value of benefits received. Governments may also institute a two-part pricing system based on a membership fee for aircraft operators plus a fee for each use.

### Recommendations for Air Links

Currently, the costs of the air navigation and traffic control systems would almost be covered by the Air Transportation Tax if all of it were allocated for these purposes. But the basis for charges under this tax, which is levied on airline passengers, is not related closely to costs imposed by the aircraft, or distance flown and size of aircraft. In addition, the charges should be levied on aircraft operators, who in turn will pass it on to passengers, since carriers and other aircraft operators make decisions about air navigation system use.

Therefore, we **recommend** that:

**5.7 A system be developed that charges aircraft operators directly to cover the cost of air navigation and traffic control. The charge should reflect costs attributable to the type of flight and class of aircraft, and value of benefits received. This system would replace the Air Transportation Tax.**

As suggested above, the basis for appropriate charges is likely to involve a combination of distance flown and size of aircraft. It may also reflect the aircraft's route or the region over which it is flying.

## RAIL LINKS

Pricing the use of rail track involves issues similar to pricing roads. With rail, however, the systems are already in place, or could be readily put in place, to allow charges to be based on the rail link used, the time of use, and the speed and weight of the train that causes wear. Railways that own their own track pay its full cost, and presumably respond to marginal costs in making pricing and operating decisions. The component of the cost of track (approximately 5 percent) represented by VIA Rail's payment, including incentives, to CN and CP for track use varies to a limited extent with tonne-kilometres travelled, depending on the link.

## WATER LINKS

Links for ferries and other vessels are open water and buoyed (and sometimes dredged) channels. The costs of water links may vary little with changes in the level of use, thus the marginal cost may be low relative to the average cost.

To minimize discouragement of use, the federal government should apply a pricing approach for water navigation links similar to that for air navigation. Charges should reflect the costs associated with different groups of users and the value of benefits received. Savings in operating cost and safety presumably vary with the size of the vessel and the distance travelled. Where practical, charges should also reflect the different navigation system costs associated with different routes or regions.

The portion of total government water navigation costs attributable to ferries is low, and we are not suggesting a special system for ferries. Currently, there is little or no recovery of water navigation costs from ferry operators and other users, but Transport Canada has made proposals to move toward recovering a substantial portion of these costs. Ferries would come under the proposed cost-recovery system in the same way as other commercial vessels, and we suggest that policy makers examine the pricing approaches we have recommended when putting such a system in place.

## APPLYING THE PRINCIPLES TO CONTROL

"Control" is the directing of traffic and policing of terminals and links. In each mode, control services involve a mix of capital and labour costs. Usually, costs are more closely related to the maximum number of vehicles the particular facility can handle than to the actual number of vehicles operating below the maximum. For example, the cost of handling one more motor vehicle, airplane, train or ship within capacity limits is likely to be small. If demand for services changes significantly, however, capacity should be adjusted, with a corresponding change in costs.

Use and provision of control services are often closely associated with use and provision of links, and it may be practical to combine the administration of pricing for links with that of control. Some control cost components are route-specific and, where practical, could be an element in establishing route-specific charges. Other control costs may not be closely related to activity on individual routes and will have to be divided among all users of a network. For example, a component of the fuel tax might be used to charge users of a provincial or territorial highway system for the costs of their police forces.

# ENDNOTES

1. There are two methods of accounting for capital costs: investment expenditures can be included in total costs in the year in which they are made, or they can be amortized over time in such a way that the stream of annual "depreciation charges" and of annual "interest charges" (or return on capital) has the same discounted present value as the initial investment expenditure. The latter approach gives a smoother stream of annual costs and provides a better estimate of the cost of using the facility in a particular year. The Royal Commission's cost analysis work uses this amortized cost approach; a real rate of return of 10 percent, applied to one-half the replacement value of the facility, is used to estimate the "interest charge."

2. The balance is attributed to general aviation. Costs of military and other government use of air infrastructure are excluded from the total being allocated.

3. Gordon B. Hamilton, "Cost Competitiveness of Canadian Airports," paper presented to Air Transport Association of Canada 57th Annual General Meeting, Vancouver, Canada, November 10-12, 1991.

4. Yarmouth has 6,000-foot (1,800 metres) and 5,000-foot (1,500 metres) strips that are 150 feet (45 metres) wide to accommodate DC-9 aircraft; Oshawa has 3,400-foot (1,000 metres) and 2,670-foot (800 metres) strips that are 100 feet (30 metres) wide to accommodate DHC-8 aircraft.

   Yarmouth is 350 km from the nearest alternative paved facility; Oshawa is 65 km.

   One fifth of Yarmouth's annual operating costs are attributable to its full on-site Emergency Response Service (which is not required under national safety standards); Oshawa depends on the local fire department.

   Control-tower costs from the longer operating hours at Oshawa are not reflected in the airport's accounts.

   Yarmouth faces frequent heavy snow; at Oshawa it is rare, and clearance is not so urgent.

   There is a 5-year-old terminal at Yarmouth; Oshawa representatives are asking the federal government to build a terminal there.

5. Electronic road pricing refers to systems that are able automatically to recognize the existence of a vehicle, and to apply a charge that may vary with location and time. The vehicle might carry a pre-paid "debit card" in the form of an electronic tag, from which the charge was deducted automatically; or an automatic link might allow the owner's bank account to be debited; or the system might send the owner a bill, like other utility bills.

6. Examples are: on Oklahoma turnpikes, the Dallas North Tollway in Texas, and the Crescent City Connection Bridge, New Orleans, Louisiana. European examples include the Oslo and Trondheim Toll Rings in Norway, the Autostrada connecting Milan, Florence, Rome and Naples in Italy, and the ACESA highway in Barcelona, Spain. These and other systems are described in T.D. Hau "Congestion Charging Mechanisms: An Evaluation of Current Practice," Transport Division, Infrastructure and Urban Development Dept., The World Bank, draft report March 23, 1992.

7. "Axle-weight" is a customary abbreviation to describe the features of heavy trucks that determine the load they impose on road structures. In reality, loads vary with a number of vehicle characteristics in addition to the number of axles, including the number and width of tires, the spacing of the axles, and the nature of the suspension. Charges should take account of as many of these aspects of truck configuration as is practical, as well as the distance travelled.

# CHAPTER 6

# MANAGING TRANSPORTATION INFRASTRUCTURE: THE INSTITUTIONS

## INTRODUCTION

In Chapter 4, we applied our principles to transportation infrastructure such as terminals, links and traffic control. We observed that:

- since carriers and other users will be asked to pay the full cost of transportation infrastructure, it is particularly important that what is provided is only what is needed;
- where there is an adequate degree of competition among various facilities in a regional market, the forces of competition should be allowed to determine levels of investment and charges, provided that such charges include the costs of accidents and environmental damage; and
- where competitive forces are not sufficient and/or users are in a weak bargaining position, regulation of prices and investment will be necessary.

Under our principles, we noted that governments would act primarily as referees in the passenger transportation system. Their role would be to:

- set and enforce standards;
- maintain competition, including assuring access to monopoly facilities by competing carriers;
- regulate prices charged by monopolies; and
- provide for research, accountability and transparency.

Where a government continues to own or operate transportation infrastructure, its refereeing responsibilities should be at arm's length from its ownership and operating responsibilities. Appointing a referee should be done in a way that enhances the referee's independence and ensures the arm's length relationship.

In Chapter 5, we developed pricing and investment approaches for infrastructure that would best achieve our objectives of fairness and efficiency. We recommended that when governments or industries consider investing in such infrastructure, they use benefit-cost analysis where, if possible, prices and revenues provide the basic measure of benefits.

In this chapter, we turn to the question of who should make investment decisions, set prices, and manage, build and maintain transportation infrastructure. We consider which features of institutions would, in general, help achieve the principles we set out in Chapter 4. We then consider a number of major institutional issues concerning specific types of infrastructure, including:

- the ownership and management of airports;
- the ownership and management of the air navigation system;
- the type of government institution that could be responsible for roads, and a possible national highway system; and
- the ownership and management of rail track.

## ALTERNATIVE INSTITUTIONAL ARRANGEMENTS

Where transportation infrastructure is provided on a monopoly or near-monopoly basis, government intervention in pricing and investment may be required. Monopoly owners can charge higher prices than those required to recover an efficient level of costs, including normal profits. These higher prices can, in turn, lead to smaller facilities, or less use of facilities, and less use of the mode of travel, than in non-monopolistic situations. Our concerns over monopoly profits apply to both privately owned and government-owned infrastructure. In the latter case, the infrastructure manager may have monopoly power over prices and little incentive for profit. This reduces the pressure to keep costs under control.

Where monopoly power is a concern, the challenge is to establish mechanisms that limit the exercise of this power without reducing the pressure for public and private firms to provide their services efficiently. There are many types of institutions that can regulate or intervene in monopoly or near-monopoly situations. In some cases, government institutions monitor private companies; in others, independent institutions monitor public companies.

## PRIVATE-SECTOR PROVIDERS OF TRANSPORTATION INFRASTRUCTURE

### Examples in Canada and Other Countries

The private sector provides transportation infrastructure largely to meet carriers' needs. Railways tend to own their track, bus companies generally own their terminals, and ferries frequently provide their own docks and wharves. While few carriers own air and road infrastructure, in the United States major air carriers have entered into residual financing arrangements with airport authorities. Under such arrangements, an airline assumes the airport's financial risk in return for long-term agreements that provide it with considerable control over investment and operations at the airport.

Governments in several countries have been attracted by the prospect of private-sector ownership of transportation infrastructure as commercial ventures. France, Italy and Spain have set up extensive systems of tolled highways under private or mixed ownership. The United Kingdom and some U.S. states, notably California, have invited private firms to participate in developing and operating a number of tolled roads, bridges and tunnels. In 1987, the governments of the United Kingdom and France awarded a monopoly franchise to a private company, Eurotunnel, to build and operate a 50-kilometre rail tunnel between Dover and Calais. There are also examples of private-sector involvement in airports.

The fixed crossing under consideration between Cape Tormentine, New Brunswick, and Borden, Prince Edward Island, is a potentially important Canadian experiment in private-sector involvement in a transportation link. The federal Department of Public Works has received bids from private-sector consortia that are prepared to build the crossing, operate it for 35 years and then transfer it to the Department. The project, estimated to cost up to $1 billion, is to be privately financed. Private investors will derive revenue from toll charges to be indexed to the provincial Consumer Price Index and from a 35-year federal subsidy. This subsidy is not to exceed the estimated cost to the federal government had it continued to operate the Cape Tormentine to Borden ferry service at the current subsidy level plus inflation.

Are private firms more efficient than governments in providing transportation infrastructure? In the case of European toll roads, where governments have had extensive experience with private-sector involvement, the evidence is mixed. Private firms appear to have performed well in managing road construction, but governments have had difficulty establishing long-term arrangements that offer sufficient incentive to private companies to maintain such roads and operate them efficiently.[1]

We also note that efficiency is not necessarily the main reason that governments turn to the private sector to provide this infrastructure. Governments are attracted by the opportunity to avoid borrowing, rather than by the possible gains in efficiency that result from transferring investment decisions and risk-taking to private operators.

### Problems with Private-Sector Providers

We believe that private ownership of transportation infrastructure can be compatible with our principles with respect to pricing and equal treatment of the modes. Transportation infrastructure, however, often requires large amounts of highly specialized investment. The result is that, in some cases, owners may gain considerable monopoly power. Government regulation will often be necessary to control the power of private firms, or autonomous public firms, and to ensure that carriers have equal access to infrastructure.

Problems of equal access arise particularly when a carrier, or a number of carriers, own or control infrastructure and can prevent entry by potential competitors. At some U.S. airports, a single carrier may have substantial influence under the residual financing arrangements. There, major carriers with long-term exclusive leases and the sole right to use scarce airport gates may block expansion of the airport and thus impede the entry of new carriers and competition.[2]

Problems of access are not exclusive to transportation, but arise in other industries such as electric utilities, natural gas and telecommunications. Governments have recognized the need to ensure access to essential infrastructure in all sectors of the economy. While there is no universally accepted definition of essential, one review of U.S. regulatory decisions[3] found that regulators tended to apply four criteria when defining essential facilities:

- The facility is controlled by a monopolist or a group of competitors with monopoly power.
- Duplicating the facility is not commercially viable.
- Denying access to the facility, or imposing restrictive terms of access, has a substantial adverse effect on competition.
- There is no valid business reason for denying access.

Based on these criteria, if a potential entrant to the market could provide its own parallel infrastructure at the same or lower cost, access would not be a problem and the infrastructure would not be considered essential. For most transportation infrastructure, however, these criteria apply and access is an issue. In the case of intercity bus terminals, new entrants denied reasonable access to an existing bus terminal can often make their own arrangements for passenger pick-up and delivery. In some locations, however, bus terminals may be essential infrastructure. The advantages of the location of the central bus terminal in a major city may be such that carriers denied access would be at a considerable competitive disadvantage.

Governments can attempt to regulate fair and equitable access, but may not be able to enforce it effectively. Transportation infrastructure owners who have an interest in preventing competition may be able to hamper new entrants with subtle impediments. The question then arises: is carrier ownership undesirable where transportation infrastructure is essential? Governments must weigh the risks of anti-competitive conduct against the gains that may result from allowing a single organization to provide both carrier and infrastructure services. Such gains could exist where there are efficiencies in making carrier and infrastructure investment decisions together, or in jointly managing infrastructure and carrier operations. This issue is particularly relevant to the current institutional arrangements for passenger rail services, which we discuss later in this chapter.

## PUBLIC-SECTOR PROVIDERS OF TRANSPORTATION INFRASTRUCTURE: THE OPTIONS

### A Government Department

In Canada, most public transportation infrastructure, including roads, air traffic control and most airports, is the direct responsibility of government departments. This has advantages in some circumstances. It allows a high degree of political direction, which may be desirable when government objectives vary and cannot be clearly articulated in advance. When close political direction is necessary, however, it is important to find ways to increase transparency and improve accountability in order to sustain our basic principles for pricing and investment decisions.

A government department is at a disadvantage when it operates infrastructure such as roads and airports. Hierarchical and bureaucratic decision making can be costly and slow, particularly when departments need to respond rapidly to changing economic circumstances (for example, in carrying out functions with large operational or commercial components). In addition, the nature of centralized budgeting means that when more spending is part of the appropriate response to circumstances, departments will not be able to provide the funds because of other political priorities, even if the users are willing to pay.

Some of the problems of government departments can be addressed by contracting out certain activities to private firms. At present, most provincial and territorial government departments contract for road construction, and many contract for road maintenance. The federal government contracts with private firms to operate some of its smaller airports.

A government department is likely to be the best choice as a provider of transportation infrastructure where the benefits of satisfying a need for close policy direction outweigh the costs of a less-efficient operating environment. A government department may also be preferred if financing the infrastructure requires taxation, which governments closely control.

### A Crown Corporation

Crown corporations have greater autonomy than government departments. They generally have boards of directors that help ensure that decision making occurs at arm's length from governments. Governments, however, may provide general direction through legislation that establishes the Crown corporation and may retain the power to give it directives on key issues.

Using Crown corporations can facilitate implementing and enforcing our principles, can promote financial transparency and can provide greater efficiency than is likely with a government department. Efficiency may increase because of the advantages of decentralized decision making and the corporation's freedom from standardized departmental rules and bureaucratic procedures. The corporation may also put an increased emphasis on commercial objectives and internal incentives to promote improved commercial performance.

The advantages of a Crown corporation, however, may not be realized if governments fail to establish an adequate regime of accountability and control. Governments must include mechanisms for monitoring the corporation's performance to ensure that its board and management are fulfilling their responsibilities and not abusing market power. At the same time, we stress that monitoring and control must be oriented toward achieving general objectives and must not become a means by which governments micro manage Crown corporations. Where effective control can be exercised, a Crown corporation may be a better institutional choice for managing some transportation infrastructure. We caution against the politicization of Crown corporations by governments, which would detract from the usefulness of a Crown corporation for managing transportation infrastructure.

### An Independent Authority

An independent authority has greater autonomy than a Crown corporation. It generally has a board of directors composed of interested parties such as users, local or regional governments, professional associations, environmental group representatives and related interest groups. The board is not subject to government directives and has full authority for pricing and investment decisions, possibly subject to a regulatory review. One type of independent authority is the Local Airport Authority established to operate some federally owned airports. Similar independent authorities could be established to operate link and control components.

User-groups represented on the board of directors can directly influence levels and quality of service. Their influence also reduces the risk that fees will be set at monopolistic levels. We note, however, that an independent authority may make decisions contrary to the wishes of groups under-represented or not represented on its board. Such groups may include carriers who desire access to a particular facility. Since government does not monitor an independent authority's performance as it does a Crown corporation's, we believe it is extremely important that the independent authority's board membership adequately represent all interested parties. This would ensure that sufficient pressure could be generated within the organization for efficient performance.

An independent authority is a good choice for providing transportation infrastructure where there would be considerable gain from limiting government influence, and where interested parties could be adequately represented on the board. These factors were influential in the creation of Local Airport Authorities, which we discuss later in this chapter.

### Choosing the Appropriate Public-Sector Institution

There is no ideal institutional structure that should be used for all types of transportation infrastructure. The appropriateness of the organization will differ depending on the mode of transportation and the type of infrastructure. The choice also depends on the nature of government objectives and the inefficiencies that may result when government is involved in activities that require frequent decisions on operational issues.

In addition, the adequacy of an institution depends not just on its type — government department, Crown corporation or independent authority — but also on the mechanisms available to promote transparency and to increase the accountability of those making decisions. We believe, however, that there are advantages in moving away from governments' current reliance on their own departments for providing transportation infrastructure. Later in this chapter, we examine the type of institution that best matches certain modes and types of infrastructure.

## PUBLIC-SECTOR PROVIDERS OF TRANSPORTATION INFRASTRUCTURE: RELATED ISSUES

### Earmarking Revenues, Borrowing, and Controlling Charges

In Chapters 4 and 5, we stated that charges for the use of infrastructure should cover the full, efficient costs of operating the infrastructure.

This in turn suggests that the revenues raised from such charges be earmarked to cover the costs of such infrastructure. Costs should include payment to governments for a return on their investment in infrastructure. As well, owners of infrastructure might need to borrow in order to finance new construction (particularly in the case of an expanding operation). The interest and principal costs of borrowing should be paid for from revenues from charges to travellers.

Earmarking revenues and undertaking project-related borrowing are natural activities of Crown corporations and independent authorities. Although such activities are not as characteristic of government departments, departmental operations in the past have made some use of earmarked funds. These include revolving funds, a limited number of earmarked taxes such as the Air Transportation Tax, and social insurance charges such as the Unemployment Insurance premium.

Many Canadians will view charges to travellers as similar to taxes, particularly when such charges are not closely related to the benefits received and where the monopoly is powerful — as in the case of providing roads. In cases such as this, government may wish to maintain direct control over pricing. If government does not maintain direct control, then an independent regulatory body would be required to review charges proposed by the road owner.

### Advisory Arrangements

Advisory bodies may be useful supplements to any type of institution, but may be especially appropriate where a government department provides transportation infrastructure. Advisory bodies offer an independent source of counsel on pricing and investment decisions, and/or provide the public with independent information on the management of the infrastructure. Advisory groups have no power to make decisions and are not sufficient if the main goal is to separate decision making from the political process. An advisory body, however, may be a realistic first step toward institutional change when issues involve policies over which governments have closely guarded their authority.

An independent source of advice can also be beneficial for public agencies or independent authorities. It can provide some balance to the natural tendency on the part of management to empire-build — to increase their scope of activities wherever possible. In addition, advisory bodies that report publicly can make an important contribution to improving the transparency of financial arrangements and decision making.

## AIRPORTS

In Canada, the federal government currently owns the major national and regional airports as well as a number of the airports used by commercial air services in small communities and remote regions. Some of the major airports are now being transferred to Local Airport Authorities.

Federally owned airports operate under various types of management. Some, including the larger airports, are being managed directly by the federal Department of Transport or by Local Airport Authorities. Some are operated by private firms under contract. Others are leased out to regions or municipalities, with or without federal subsidies. Terminal 3 at Lester B. Pearson International Airport in Toronto is unique. It was developed and financed, and is being operated, by a private firm under a long-term lease agreement with the federal government.

As well, there are municipally owned airports such as Edmonton Municipal (one of the ten busiest airports in Canada) and privately owned airports such as Buttonville in Toronto.

Many other countries do not use government departments to operate major airports. Institutional arrangements vary:

- In the United States, major airports are run by municipal or county governments, or by airport or port authorities.[4]

- In the United Kingdom, seven major airports — Heathrow, Gatwick, Stansted, Prestwick, Glasgow, Edinburgh and Aberdeen — are now owned and operated by a private sector company (BAA plc). Smaller U.K. airports are owned by local city councils, private firms or, as in Liverpool, by both.
- In Germany, the 11 main airports are operated by independent companies, with the federal government as a minority shareholder in each airport corporation.
- Australia has a centralized institutional structure, but since 1986 the major airports have been managed by the Federal Airports Corporation, a Crown corporation with a commercial mandate.

## LOCAL AIRPORT AUTHORITIES (LAAs)

In Canada, the federal government is reducing its role in airport operations by transferring the operation of several major airports to Local Airport Authorities. Its objectives in so doing are "to make airports serve local community interests better and to allow our national airport system to operate in a more cost-efficient and commercial manner."[5] Currently, federally owned airports in Vancouver, Calgary, Edmonton and Montreal have been or are being transferred to LAAs, and several other large federal airports are expected to be considered for transfer.

### The Role of LAAs

LAAs are independent bodies that can enter into contracts, issue debentures, sue and be sued. Unlike private corporations, LAAs do not have shareholders. The Board of Directors runs the LAA and has responsibility for establishing objectives and policies, approving plans and budgets, and overseeing the performance of management. The enabling legislation or articles of incorporation for an LAA specify which governments and organizations may appoint board members. The nomination of elected government officials or government employees is prohibited.

The federal government has a continuing responsibility for air navigation and safety at LAA airports, and remains a landlord, leasing airports to the LAA on a long-term basis. The LAA operates the airport and assumes full responsibility for any financial liabilities it incurs. LAAs are expected to achieve financial viability by setting their own rates and developing the commercial potential of the airport. LAAs have 60-year leases with a rental formula that allows the federal government to share in any growth in gross revenue above a base-case forecast. Under this formula, the federal government should be no worse off financially, and potentially better off, than it would have been had it continued to operate the airport.

## Potential Monopoly Power of LAAs and Other Major Airports

Federal policy concerning LAAs does not include any explicit provision to control monopoly power. We believe that it is important to look at the potential for non-competitive pricing of landing rights by local authorities.

The potential for non-competitive pricing is enhanced by the fact that landing fees generally constitute a small portion of flight costs; this tends to cause carrier demand for landing rights to be relatively unresponsive to increases in landing fees. The market power of the LAAs also depends on the opportunity for carriers and other users to switch to another airport. For example, if Airport B is a close substitute for Airport A, any attempt by A to unilaterally raise its landing fees would have a detrimental effect on its traffic. In practice, however, the ability of airlines in Canada to use alternative airports is limited. For non-connecting traffic, which constitutes around 70 percent of the traffic at most Canadian airports, airlines have an alternative only when a second relatively uncongested airport is in close proximity. Few Canadian centres have two or more airports that are in a position to compete with each other for such traffic. The result is that, in general, airlines have few opportunities to switch airports if LAAs abuse their market power by setting excessively high landing fees.

The possibility that carrier access could be restricted at airports under LAA control also warrants examination. Transport Canada officials argue that the interest of the local community is in promoting access by as many carriers flying to as many locations as possible. An LAA might, however, find that, in principle, it could maximize its own revenue by awarding a long-term exclusive lease to a single carrier who would be willing to pay a price for the exclusive lease, which would allow it to earn monopoly profits. This arrangement would limit local residents' choice of airlines. Under these circumstances, the onus would be on the Director of Investigation and Research in the federal Department of Consumer and Corporate Affairs to enforce the prohibitions in Canada's *Competition Act* against exclusive contracts and discrimination in supply.

We believe that the nature of LAA boards and the *Competition Act* provide considerable protection against monopoly pricing and, in particular, limitation of access to competing carriers. At this stage, we do not recommend establishing a referee with review powers over LAA pricing. LAA pricing, however, should be monitored by the National Transportation Agency on behalf of the federal government.

## THE IMPACT OF FEDERAL POLICIES ON COSTS

Federal control may increase operating costs at Canadian airports because of:

- delays in making new investments where expansion is justified;
- administrative overhead;
- operating standards that are inappropriate for and that substantially increase costs at smaller federal airports; and
- inflexibilities associated with federal labour practices.

The problem of inappropriate common standards is illustrated by the government policy of having separate Emergency Response Services (ERS) available on-site at even the smallest federally operated airport with scheduled commercial flights. For example, at Yarmouth, Nova Scotia (a federally operated airport), approximately one fifth of operating expenditures are associated with maintaining on-site ERS. By comparison, Oshawa, Ontario (a non-federally operated airport with similar traffic levels) relies on the local fire department and incurs no ERS expenses. Oshawa's total operating expenses are about one-quarter Yarmouth's. The higher ERS costs at Yarmouth are not due to poorer performance by airport staff, but to costs associated with federal airport policy.[6]

The impact of federal work rules was illustrated in a 1985 report by the Auditor General of Canada that compared airport maintenance at three U.S. airports with that of three similar Canadian, federally operated airports. The report found that labour requirements at the U.S. airports were 40 percent lower. While employees at U.S. airports performed a variety of functions, Canadian workers were hired for specific maintenance functions. The result was lower labour productivity and higher operating costs.[7]

## GUIDELINES FOR AIRPORT REFORM

Investment in federal airports has been influenced by the federal government's financial position. We believe it is important for the airports to be self-financing in all aspects, including air traffic control.

Local control of federal airports will alleviate some of the problems of the current system. Decentralized decision making will allow airport management to pay greater attention to the preferences of residents of the region served by the airport, who are also the primary users of the airport and bear the consequences and reap the benefits of new airport development. Decentralized decision making should also contribute to greater transparency. Users can see more clearly what they are paying for in a system where there is a direct connection between charges to travellers and capital spending.

Therefore, we **recommend** that:

---

**6.1 The federal government proceed quickly with the transfer of all remaining federal airports to local airport authorities and/or to other types of local operators.**

---

## AIR NAVIGATION

Canada's air navigation system has been under increasing pressure from the growth in air traffic following deregulation of the airline industry and increased activity at certain hub airports. In our hearings, speakers expressed concern that air traffic operations are underfunded and, therefore, cannot adequately respond to market demands. In July 1991, the Air Transport Association of Canada, the Canadian Airline Pilots Association, the Canadian Air Traffic Controllers Association and the Canadian Business Aircraft Association observed, in a letter to the federal Minister and Deputy Minister of Transport, that "the present Air Traffic Control System is not serving the interests of the travelling public, pilots nor the aviation industry and is creating a progressively higher level of frustration in employees working the system who wish to perform a professional service."

The federal government has responded. In particular, Transport Canada is looking at ways to increase the number of licensed air traffic controllers, and has developed a comprehensive plan to meet requirements for controllers by July 1994.

We believe, however, that these issues reflect fundamental deficiencies in Canada's current organizational arrangements for air navigation. Stress on the system would be reduced in an environment where managers had greater operational freedom and access to revenue that allowed them to respond to changing requirements. The 1991 final report of the Ministerial Task Force on Aviation Matters expressed the issue thus: "The public service environment with its restraints, slow and complicated processes, uncertainty of funding within the government's competing demands and lengthy decision-making processes seemingly inherent in a civil service does not correspond to the dynamic environment in which aviation operates. All of these factors combine to limit the flexibility of the department and reduce its ability to respond quickly and effectively to the ever-growing demands of the aviation community."[8]

In the United States, the Federal Aviation Administration (FAA) has somewhat greater operational freedom than its Canadian counterpart, although it is still part of the U.S. Department of Transportation. A number of other countries — Australia, New Zealand, the United Kingdom and Germany — are establishing their air navigation systems with independent status. The Ministerial Task Force on Aviation Matters also favours this general approach.

We therefore **recommend** that:

---

**6.2 The federal government convert the air navigation system from a departmental organization to either a Crown corporation or an independent institution.**

---

An independent institution, separate from government, is consistent with, and complementary to, our proposal in Chapter 5 that airline companies pay the full costs of air navigation. Such an organization might be a publicly owned independent authority or a private corporation owned jointly by airline companies. A user-funded institution free from the restrictions that apply to government departments would be in a better position to meet the requirements of the airline industry.

## THE ROLE OF THE FEDERAL GOVERNMENT

Under our proposal, Transport Canada would continue to ensure that the air navigation system meets appropriate safety standards. The federal government must also be in a position to ensure that international obligations to provide access to foreign carriers, and to comply with international technical standards, are met.

In addition, if air navigation is assigned to a Crown corporation, the federal government would be responsible for monitoring activities and reviewing performance, as it does with all federal corporations subject to the *Financial Administration Act*. Since the proposed agency would be a monopoly, albeit a public monopoly, one of the purposes of federal review would be to ensure that the agency did not abuse its monopoly powers.

## AN INDEPENDENT INSTITUTION

An alternative to a Crown corporation would be a private corporation, jointly owned by the users, with the federal government still responsible for regulating safety. Since such a corporation would be responsible to its owners, who are also users, it would be less likely to exploit its monopoly position. Its owners and users would want the highest level of service at the lowest possible cost.

We see advantages in a privately owned, user-operated air navigation system that is subject to government safety regulation. Before such a system could be implemented, however, the federal government must ensure that the interests of all stakeholders are adequately represented. For example, those with a minor, or no, position in the corporation (such as small carriers or general aviation) must not be discriminated against. The system must also be set up in a way that precludes it from being able to put potential new entrants to the airline industry at a disadvantage. If the independent institution's charter does not give adequate representation to all these interests, the federal government should appoint a referee. If the federal government is unable to establish a private corporation that gives adequate protection to all interested parties, a Crown corporation would be preferable to an independent institution.

## ROADS

Highway networks are unlikely to be privatized or turned over fully to independent authorities in the near future. A major role for Crown corporations with a considerable degree of independence holds more immediate promise. Governments have traditionally retained close control over the extent and location of roads and the charges for their use. Road pricing will probably continue to take the form of fuel charges and licence fees, supplemented by weight-distance charges on trucks. All of these charges are generally uniform within a province.

With uniform charges, prices and revenues provide limited guidance in assessing specific road investment decisions. Toll roads are the exception. Pricing can then be specific to individual links, and prices and revenues can provide a basis for investment decisions.

While governments are likely to retain responsibility for decision making, they should be more accountable and the nature and implications of decisions should be more transparent. Road users should have information that will enable them to assess whether the highway system is being efficiently managed through appropriate decisions on investments and maintenance.

### TRANSIT NEW ZEALAND: A MODEL

In 1989, the New Zealand government created Transit New Zealand, an institution established outside the departmental structure in order to remove political influence from expenditure decisions. Transit New Zealand coordinates road planning and provides independent advice on road revenue policy and road expenditures. Although the Minister of Transport must approve its annual revenue and expenditure proposals, these proposals carry considerable weight as a result of Transit New Zealand's extensive system of consultation and highly transparent system of road planning.

Transit New Zealand develops an annual National Land Transport Programme, drawing on plans developed in each of the 14 regions of New Zealand. These plans are based on decisions made at the local level. The Land Transport Fund, managed by Transit New Zealand, finances expenditures and provides all participants in the system with a clear picture of revenues and expenditures.[9] Revenues come from fuel taxes, other charges to road users (including a weight-distance charge for heavier trucks), and motor-vehicle registration and licensing fees.

## GUIDELINES FOR PROVINCIAL AND TERRITORIAL ROAD AGENCIES

New Zealand's approach shows how a Crown corporation can be used to encourage greater efficiency, and to increase accountability and transparency in pricing and investment decisions.

We therefore **recommend** that:

**6.3 Each provincial and territorial government establish a Crown corporation, supplemented by an advisory group, to provide roads more efficiently and to make road pricing and investment decisions more transparent.**

The advisory bodies should include specific user-groups as well as other groups that have system-wide interests, such as those concerned with the environment. The mandate of the advisory body should be broad enough to include links between the roads and other modes of transport.

We expect that most provincial or territorial governments would wish to retain final authority over levels of fuel tax, motor-vehicle licence fees and weight-distance charges. But we suggest that provincial and territorial governments make decisions on these charges in response to proposals from their road agencies, which would recommend levels for the charges together with road investment plans.

Under our principles, revenues from charges to travellers transferred to a road agency should be related to use of the roads for which the agency is responsible. For example, if a road agency is responsible for building and maintaining provincial but not municipal roads, revenues related to the use of municipal roads should be handled separately.

The provincial government would allocate, as accurately as possible, the portion of total fuel-tax revenues in a province to a "road account." It should also consider applying a fuel tax to cover road-related policing costs, traffic control and some health system costs (Chapter 8). In addition, the provincial or territorial government may be the appropriate level of government to apply some environmental charges (Chapter 7).

## THE NATIONAL HIGHWAY SYSTEM PROPOSAL

The Federal-Provincial Council of Ministers Responsible for Transportation and Highway Safety is currently studying a National Highway Policy proposal. The proposal would designate, as the National Highway System (NHS), a network of highways linking provincial and territorial capital cities, other main population centres, major ports and U.S. border crossings. The network would be almost 25,000 kilometres in length, compared with 7,300 kilometres for the Trans-Canada Highway.

The proposal suggests that the network be upgraded "to bring cohesiveness, prestige and uniformity of standards to the major highway transportation linkages of national significance in Canada."[10] Minimum standards would include:

- a design speed of 100 kilometres per hour — that is, highway alignment and shoulders sufficient to allow 100 kilometres per hour operating speed;
- sufficient capacity to handle the volume of traffic expected without average speed falling below 90 kilometres per hour;
- bridge and road strength adequate to handle traffic without seasonal weight restrictions; and
- road surfaces to meet a consistent measure of ride smoothness.

According to studies performed for the Council of Ministers Responsible for Transportation and Highway Safety, many existing highways that would form part of the intended network do not meet these standards. They found that:

- about one third of its length does not meet the proposed minimum standard for 100 kilometres per hour design speed because of inadequate width, alignment, or shoulders;
- about 19 percent of the network is at times too congested to allow 90 kilometres per hour continuous operation;
- almost 16 percent of the network has load restrictions and requires pavement or bridge reconstruction to handle the maximum loads allowed under national standards; and
- about 16 percent of the network needs resurfacing to meet the proposed standard for ride smoothness.

In total, about 9,500 kilometres of the proposed 25,000-kilometre network would not meet one or more of the proposed minimum standards, and 790 bridges would need strengthening.

### The Costs of Upgrading the NHS Network

The National Highway Policy proposal has identified all of the upgrades that would be required to meet these standards — some

2,000 separate projects with a total estimated cost of $12.7 billion in 1989 prices. A secondary proposal under consideration would add the twinning of all remaining sections of the Trans-Canada Highway for an additional cost of $4.8 billion in 1989 prices.

The Council of Ministers Responsible for Transportation and Highway Safety is examining whether the federal, provincial and territorial governments can reach a cost-sharing agreement to allow adoption of these proposals.

### Assessing the NHS Proposal Using Our Principles

We believe that governments should assess the NHS proposal using our principles for investment decisions, and provide financial support for component projects only if the benefits exceed the costs and if the project can be paid for by the travellers who use it. Governments should also compare these projects with possible investments in other modes and other locations. Approved NHS projects should then be financed by charges to road users.

An analysis of the NHS showed that the proposal as a whole would not meet the benefit-cost test.[11] Using Transport Canada's standard valuations of benefits, it appears that the costs of upgrading the network to the proposed uniform standards exceed expected benefits, and that the additional proposal to twin the remainder of the Trans-Canada Highway would increase the net loss substantially.

Some of the projects, however, could produce substantial net benefits over their costs. For example, many of the maintenance projects for existing roads, such as bridge rehabilitation and highway resurfacing, are more beneficial than many proposed investments in building new lanes or widening existing highways. In addition, the proposed improvements most easily meet the benefit-cost test for the more intensively used parts of the network, (generally located in more populated regions of the country).

We believe that, rather than trying to make a decision on the proposal as a whole, projects should be rigorously evaluated on an individual basis. Governments should establish priorities for those projects that pass a benefit-cost test. We see the National Highway Policy proposal as an example of the potential for excessive spending that can arise when common national standards and engineering conventions are emphasized, but little attention is given to assessing the economic benefits and costs of individual projects.

### Recommendations for the National Highway System

The proposed minimum standards would require a substantial expansion of capacity for many low-volume roads. The failure of many of the proposed projects to meet a benefit-cost test, however, demonstrates that the proposed engineering standards are not appropriate to all highways and traffic conditions. On those parts of the network with less traffic, some more-modest upgrading projects, to meet standards of capacity and performance somewhat less rigorous than those applied to roads with higher volumes of traffic, might be sufficient. To achieve efficiency, governments should tailor solutions to local conditions.

Therefore, we **recommend** that:

---

**6.4 The extent of restoration and upgrading of the national highway network be guided by comparison of benefits and costs on individual projects, rather than by uniform engineering standards.**

---

Our rejection of the minimum engineering design standards in the NHS proposal does not mean that the entire proposal should be abandoned. We believe there are advantages to be gained from designating a National Highway System and giving it maintenance priority, special markings and uniform signs. Both carriers and travellers would gain from using a system of interconnected roads of predictable quality.

We believe the proposed network is viable because it could generate sufficient revenue from users to pay for maintenance and upgrading. We do not believe, however, that all of the upgrading in the current proposal is necessary. Outside the most populated areas, there is substantial excess capacity in Canada's highway system. It would not make sense to increase that capacity still further to meet arbitrarily set minimum engineering standards. Upgrading should concentrate on the existing and potential problem areas.

The National Highway System could be operated by a Crown corporation, raising its funds through charges to travellers using the designated network or receiving appropriate transfers of the fuel taxes and registration fees from governments. Such an agency could provide users with a clear picture of road costs and provide a mechanism for formal consultations. We believe, however, that the key improvements in this highway network could be achieved by simpler forms of coordination on the part of provincial and territorial governments and/or their road agencies.

Therefore, we **recommend** that:

**6.5 A National Highway System (NHS) be identified by the Council of Ministers Responsible for Transportation and Highway Safety, and the system be operated and maintained through cooperative action of provincial and territorial governments and/or their road agencies.**

We also believe that the rationale is weak for funding projects through a national charge to all travellers or federal-provincial cost-sharing. The projects on the proposed network that meet a benefit-cost test are concentrated in Central Canada, where the population is densest, rather than spread equally across the country. The funding of such projects should be the responsibility of travellers in those regions that benefit from these investments.

Therefore, we **recommend** that:

---

**6.6 Provincial and territorial governments meet the costs of their highway system, and any agreed upon National Highway System projects within their borders, through fuel taxes and other charges.**

---

Under our principles, the federal government would no longer raise revenues from fuel taxes, except as an environmental charge on fuels (Recommendation 5.4).

We expect that examining the benefits and costs of all road projects will indicate that most worthwhile NHS projects can be financed by provincial or territorial governments using monies that might have been spent on other, lower-priority road projects.

## CONTROL OF RAIL TRACKS, STATIONS AND TRAINS

Rail is different from other modes of transportation because individual carriers often own the rights-of-way, track, and train-movement control systems. We are concerned about two rail issues:

- how ownership of the track influences competition to provide rail passenger and freight services; and
- how the need for rationalization of track networks can be met. Such rationalization raises the issue of rights-of-way abandonment, which we highlighted in our Interim Report.

### OWNERSHIP AND COMPETITION ISSUES

Is open access compromised when rail carriers own essential transportation infrastructure? Under our principles, open access to essential facilities is intended to promote competition. While we realize that it will often be impractical in all cases to provide competing rail infrastructure, we believe that considerable benefits of competition may still be obtained by allowing more than one carrier to use the existing track.

A freight or passenger carrier that owns track may create an entry barrier to new rail carriers and may impede the operations of competitive carriers. A new carrier can only enter passenger rail or freight carriage if it can negotiate reasonable terms of access with a track owner who may also be a competitor. Rail carriers thus tend not to be subject to the discipline that, in other modes, comes from the threat of entry.

Direct competition is less likely to occur in passenger rail than in freight carriage because unsubsidized passenger service has not been profitable. We are still concerned, however, that there be sufficient access for new carriers in passenger rail should they wish to enter the markets. Convenient entry for a carrier would ensure that passenger rail is given the opportunity to demonstrate its strengths in instances where it has a chance of being viable.

Passenger rail can be complementary to freight, because both services share the cost of the track. It can, however, compete with freight on heavily used segments of the track where the two users have conflicting requirements. This conflict accounts for some of VIA Rail's difficulties in obtaining optimal track access. As well, the federal government requires VIA Rail to service certain markets, putting VIA Rail in a weak bargaining position. It cannot refuse to deal with CN or CP simply because their services or rates for track usage are unacceptable.

## IMPROVING ACCESS TO RAIL TRACKS

Steps can be taken to improve access to rail tracks for new entrants and others willing to pay their share of the costs, by:

- establishing stronger legislative provisions and regulatory procedures to promote access; and

- if such legislation proves insufficient, separating ownership of track and carrier operations by restructuring CN and CP.

Separation could be achieved by creating a public or a private track corporation that would own and manage the national track network.

### Improving Access through Legislation and Regulation

Running rights, the rights that allow one railway company to operate over the tracks of another company, have a long history in Canada. Legislation on running rights from the earlier *Railway Act* was incorporated into the *National Transportation Act, 1987*. Under this Act, the National Transportation Agency can order one railway company to provide running rights to another if the two railway companies cannot work out an agreement on their own, and if the Agency deems access to be in the public interest. This provision, however, is contained in a section of the NTA, 1987, that applies exclusively to rail freight.

Therefore, we **recommend** that:

**6.7 Legislation on track access also apply to passenger rail, so that all qualified carriers willing to pay for what they use have a right of access to essential rail infrastructure and to equal treatment in movement of rail traffic.**

Unless the owner can prove that running rights would create unresolvable operational problems in a particular situation, the legislation should require the National Transportation Agency to agree to an application for access by all carriers that are "fit, willing and able" to use the infrastructure.

The technological, dispatch and traffic control issues associated with opening the track to multiple users are not a problem unless the owner of the track also happens to be a user in competition with other users of that same track. As for other modes, especially air, sophisticated techniques of traffic control are available. In addition, the rail industry has had considerable experience with trackage rights and joint agreements that raise many of the same issues. In negotiating these arrangements, railway companies have had to work out operating rules, establish track priorities and apportion liability. We see little evidence that the resolution of these issues has resulted in operational problems.

Improved legislation, however, may not be sufficient to solve certain problems of access. For example, a railway company could allow other carriers access to its tracks but establish rates or conditions that would make use of the track highly unattractive. A host railway can also substantially disadvantage a potential competitor through its traffic control and dispatch operations.

While the National Transportation Agency can attempt to guard against such anti-competitive practices, a track owner could abuse its monopoly position in subtle ways. In addition, it is difficult for a regulator to determine a reasonable track charge that is fair to the owner but does not disadvantage the user.

A number of countries require their state-owned railways to develop separate accounts that identify the costs of the track and control components of their operations. The Council of the European Communities is asking member states "to ensure that the accounts for business relating to the provision of transport services and those relating to the management of railway infrastructure are kept separate. . . ."[12] The Council believes this separation will promote fair charges to travellers and facilitate cross-border movement by the carriers of member countries.

Appropriate legislation, combined with adequate enforcement of regulations, provides the most direct solution to problems of access.

By strengthening and broadening existing provisions on running rights, the federal government would be building on an approach that is well understood by the railways and the National Transportation Agency. Nevertheless, we are not entirely convinced that legislation and regulation will prove adequate. Where a railway has an interest in restricting access, the regulatory authority might find it difficult to ensure that the new entrant is provided with a neutral opportunity, including fair treatment by the dispatch system.[13] We expect that the track owner will have more information than the regulator, and the regulator will be at a disadvantage in attempting to enforce equal access.

### Improving Access by Separating Ownership of Track and Carrier Operations

We considered the possibility of restructuring CN and CP to divide ownership of track and carrier operations (as in the road and air modes). Such a separation has its precedents:

- The earliest railways in the United States operated fixed ways that others paid to use, as did the other transportation modes of the era (turnpikes and canals).
- In 1989, the Swedish government split its state railway into two separate organizations: a public enterprise that is responsible for offering railway transportation services, and a second public agency, the National Rail Administration that is responsible for providing rail track and control systems. Sweden's restructuring was intended to put rail on a basis more comparable with the road mode, and the National Rail Administration is modelled on that country's National Road Administration. The Swedish government believes that separating track ownership from commercial carrier services, and the greater transparency resulting from the new arrangement, will increase pressure on the national rail carrier to improve operating efficiency. The government also hopes that, over the long term, new rail carriers will enter the market and consumers will benefit from the introduction of competition.

A system of separate ownership would result in the loss of savings, if any, associated with the joint provision of rail track and carrier operations. Government would have to decide whether such savings are important enough to offset the benefits from enhanced competition. The available evidence, while limited, does not suggest that there are major economies when carriers own railway track.

While we believe it is feasible to establish a separate track corporation, a structural reform of this nature is a major undertaking. Sweden's experience is not entirely applicable to Canada, because Canadian track is owned by a number of public and private corporations, rather than just one public corporation. Rail restructuring is much less complicated when there is a single public carrier, and when the national government has the authority to implement the reorganization required to improve use of the track.

If the Government of Canada were to undertake such an initiative, and if it felt the infrastructure should be publicly owned, it would have to acquire track that it does not already own. This process could entail difficult negotiations with owners over compensation. Both CN and CP would be primarily freight carriers with neither owning railway track. At that point, CN should be privatized to create fair competition for CP, and the proceeds of the sale would help pay for the purchase of the CP infrastructure.

Determining appropriate charges for track use would also be difficult. CN and CP own extensive track in the United States. Track fees and charges at a level required to cover the costs of a track corporation might result in CN and CP diverting traffic to alternative U.S. routes. This diversion could be greater on some network segments (primarily traffic to and from the west) than on others (traffic that moves within Ontario, Quebec and the Maritimes).

### Should a Separate Rail Track Agency be Public or Private?

If experience with enhanced track access is unsatisfactory and the federal government determines that separation of rail ownership and carrier operations should be implemented, the government would have to decide if track ownership would be best transferred to a Crown corporation or a private corporation. Whether public or private, the new organization must be regulated in such a way that it could not abuse its monopoly position.

In the case of a private corporation, the federal government would have to put together a package that appealed to private investors and could attract the large amount of financial capital required. The federal government would otherwise have to make certain commitments to reduce the risks from unanticipated policy change that the corporation would otherwise face. With a Crown corporation, the federal government would not have to limit its freedom in this way. In addition, the federal government's extensive holdings of track and rights-of-way through CN and VIA Rail could be transferred to the public track agency and provide the assets required to launch its operations. We thus conclude that, should separation be favoured, a public track agency is likely to prove appropriate.

In Canada, separating ownership of rail track and carrier operations is more important as a freight issue than as a passenger issue, because freight traffic dominates Canadian rail activity. Freight transportation is not the focus of our mandate, and we have not attempted to investigate, or explore with the various parties involved, the full range of questions that must be answered before a decision on separation can be made. Nevertheless, we view effective open access and equal treatment of traffic as vital. Should the application of Recommendation 6.7 — that legislation on track access be strengthened and apply to passenger rail as well as freight — not prove satisfactory, then we would recommend that the federal government separate ownership of track and dispatch from carrier operations.

If the federal government decides that separation is necessary, the best approach may be a step-by-step introduction of change. The process could begin with a segment of the network that would be a good choice for rail rationalization. For example, a public track agency could be established with responsibility for CN's and VIA Rail's rights-of-way and track in the Toronto–Ottawa–Montreal triangle. At the same time, the federal government could negotiate with CP so that the authority of the new agency could extend to all track in the region. The intention would be to rationalize track use in that region.

This first step would allow the federal government to test separation, and at the same time initiate rationalization of track use in the Toronto–Ottawa–Montreal triangle. If this experience shows that separation is beneficial, the scope of the track agency's operations could be extended to include the rail network running through Quebec and the Maritimes, where rationalization also seems warranted. The federal government could then consider a final phase of reform involving transferring track in the rest of the country to the track agency.

## RAIL RATIONALIZATION

Rationalization is not a new issue. As far back as 1931, the Royal Commission on Railways and Transportation in Canada found significant duplications among CN and CP railway systems. The Commission noted that there were twice as many miles of track per capita in Canada as in the United States, and that changing markets, competition and technology had decreased the need for railway infrastructure.

Canada's railways still suffer from low traffic density. On all but a few routes, Canadian railways could handle many more trains on their tracks. There are two ways to improve the financial position of the railways: increase traffic and operations and rationalize the track system.

With respect to increasing traffic, we expect that when governments apply our recommendations concerning road pricing, the competitive position of the railways will improve. Some freight that now moves by truck would shift to rail.

Rationalization and joint track usage have been the subject of sporadic, unsuccessful negotiation between CN and CP for many decades. The *Canadian National–Canadian Pacific Act, 1933*, that followed the 1931 Royal Commission, encouraged cooperation between the railways, including joint track usage. The NTA, 1987, included provision for joint track usage, but has not stimulated significant rationalization.

Rationalizing the track system could be approached in three non-exclusive ways that could vary from region to region. These are:

- line abandonment and joint track usage;
- divestiture of the local branch-line systems of each or both companies, and their reorganization as local short-line companies; and
- consolidation of CN's and CP's freight operations, either regionally or nationally.

### Line Abandonment and Joint Track Usage

The distinction between line abandonment and disposition of rights-of-way should be clear. We have no quarrel with the right of a railway to abandon part or all of a line. Our concern is what happens to that corridor after it has been abandoned as a functioning line; in the past, too many corridors have been sold for commercial purposes or for usage other than transportation. We firmly believe that these should be conserved for future transportation use, for example in the form of linear parks, and that governments or other railways should have first call when corridors are abandoned.

To what extent might abandonment improve the financial positions of the railways? In terms of branch lines, abandoning the lines in the prairie network that compete with road to serve the grain industry alone would generate important savings. A recent estimate suggests that abandoning selected prairie lines could result in annual savings of about $25 million.[14] For the rest of the networks, the prospects for saving through abandoning local branch lines, as opposed to abandoning whole regional systems such as in the Maritimes, are limited to a few million dollars annually.

Joint usage of main lines would boost efficiency and savings for the railways more than abandoning low-density branch lines. Closing branch lines causes traffic to shift from rail to road, but main lines could be rationalized with little loss of traffic. A more efficient railway track system might actually lead to an increase in the use of railway transport.

Substantial savings would occur if rationalization took place on the track that stretches from Winnipeg to the Ottawa Valley. For a capital investment of approximately $100 million, CN and CP could operate through this region over common track, saving 2,200 kilometres of mostly main-line track and eventually realizing savings of $50 million annually.[15]

We believe that this rationalization is desirable. We noted in our Interim Report, however, that line abandonment could lead to the loss of transportation corridors for future use.[16] Potentially important corridors in and near urban areas have already been lost through abandonment and cannot be replaced.

The *National Transportation Act, 1987*, contains a provision, which expires in 1993, whereby railway companies can apply to the National Transportation Agency to abandon up to 4 percent of their non-grain-related trackage annually. The Agency must agree to an abandonment application if the rail line is not economically viable and has no reasonable probability of becoming so in the future. As we noted in our Interim Report, under the NTA, 1987, the Agency determines the role and value of rail infrastructure in terms of its contribution to the movement of freight.[17]

The abandonment application procedures have recently been amended. A railway applying to abandon operation of a line must formally notify, among others, the federal and relevant provincial and municipal governments, other railways operating nearby and VIA Rail.

The legislated process does not provide for the long-term implications of the loss of track for passenger service or for rights-of-way for future transportation use.

We want to ensure that there are formal procedures for the disposal of rights-of-way after a rail line has been abandoned, and that this process gives governments an opportunity to acquire the rights-of-way if appropriate. Although railway officials told us that they offer abandoned rights-of-way to successive levels of government, the process is informal and inconsistent. In addition, the railways do not always put abandoned rights-of-way in urban areas up for sale. Instead, they retain and develop the lands commercially themselves. It is these urban rights-of-way that cause us the most concern.

We conclude from our review of line abandonment that:

- there should be formal procedures, regularly followed, by which all abandoned rights-of-way are offered to governments;
- governments should have established policies by which they are able to identify, acquire and retain rights-of-way that may be valuable for future use; and
- there should be rules to ensure that the price to governments of acquiring identified rights-of-way is reasonable, considering the historical use of the land as a corridor.

We believe that railways should be allowed to cease unprofitable activities, but rights-of-way that may be useful to others must be preserved.

Transport Canada has brought the concerns that were raised in our Interim Report to the attention of a federal-provincial steering committee that has been asked by the federal and provincial/territorial ministers of transport to identify a national rail network. The mandate of this committee includes reviewing policies and procedures to address concerns with rail line abandonment. Transport Canada has also indicated that it hopes to put in place an interim notice and response process and to develop long-term policy options. Although it is too early to say what the outcome of all this work will be, we believe that changes are required.

Therefore, we **recommend** that:

---

**6.8 Any railway company be allowed to abandon any amount of track without a limit and that clause 159(4) of the *National Transportation Act, 1987* not be reenacted.**

We further **recommend** that:

---

**6.9 Adequate protection of rights-of-way of potential value as future transportation corridors be assured by requiring that:**

**(a) as a condition of track abandonment, the abandoned right-of-way be offered in all cases, formally and in writing, to each level of government (federal, provincial, local), in succession, and then to other railway companies at a price equal, in all cases, to the railway's historical acquisition cost of the land adjusted for inflation, with an adequate time period for response;**

**(b) the National Transportation Agency be a referee to ensure that the price at which the land is offered is reasonable;**

**(c) only if no government or railway company wishes to purchase the corridor could the railway either convert or sell the land for purposes other than transportation;**

**(d) all levels of government develop a policy, based on explicit criteria, for deciding which corridors they wish to retain; and**

**(e) governments or railway companies maintain land so acquired as a corridor. Should they no longer wish to maintain the corridor in the future, the land be first offered back to the railway from which it was purchased, at the original purchase price plus inflation.**

# CHAPTER 7

# PROTECTING THE ENVIRONMENT

## INTRODUCTION

Passenger transportation affects the environment locally, nationally and globally. Noise pollution disturbs city residents and those living near airports; air pollution damages buildings and affects the health of people, animals and vegetation; and the greenhouse effect threatens the world's ecosystems.

One of the key objectives of our proposed passenger transportation framework is to achieve a system that automatically gives weight to the need to protect the environment. We believe that this can best be accomplished if users pay for the full costs of passenger transportation — including the environmental costs associated with different modes of travel.

At present, travellers and carriers do not pay for all the damage they cause to the environment. In fact, they cover only some of the costs of their transportation choices. Often, the decisions they make concerning how they will travel and which vehicle to purchase do not take into account the environmental repercussions of these choices. Meanwhile, others bear the costs of the damage done by travellers. As noted in Chapter 6, agencies that evaluate transportation investment proposals should consider the costs of environmental damage.

There are, however, many difficulties in trying to measure environmental damage, estimate costs and determine how users should be charged. We realize that protecting the environment may require more than charges to travellers. Regulations, particularly in the area of motor-vehicle emissions, have been instrumental in reducing gases and particulates that damage the environment.

We examined ways of assessing environmental damage and estimating costs. We asked ourselves how much governments should regulate and how much travellers should pay. Then we looked for solutions that would impose an even burden on each mode of travel and that would help Canadians achieve a balance between their passenger transportation needs and the need to protect the environment.

## HOW TRANSPORTATION CONTRIBUTES TO ENVIRONMENTAL DAMAGE

We studied environmental effects and conferred extensively with environmental experts. Much of the information we gathered, including how transportation contributes to environmental damage and the nature of that damage, can be found in Volume 2 of this report. In this chapter, we would like to focus attention on the three transportation-related environmental problems that we consider to be the most significant: low-level ozone, urban sprawl and global warming. Other significant transportation-related environmental problems, including those associated with carbon monoxide and particulates, receive very limited mention in this chapter because they are fundamentally problems of urban, rather than intercity, passenger transportation.

### LOW-LEVEL OZONE INDUCING EMISSIONS

Low-level ozone, an important component of smog, is formed when two types of chemicals in fuel emissions — nitrogen oxides ($NO_x$) and volatile organic compounds (VOCs) — act together in the presence of heat and sunlight. Low-level ozone causes respiratory problems, particularly among asthmatics, and damages the foliage of crops and trees.

Transportation contributes about 40 percent of Canada's non-natural emissions of VOCs and 60 percent of its $NO_x$. Diesel-engined trucks and buses make a disproportionately large contribution, yet are subject to far less stringent emission controls than cars.

Although low-level ozone breaks down over a period of hours or days, concentrations can build up where industrial and transportation emissions of $NO_x$ and VOCs are greatest. In addition, low-level ozone, which is wind-borne, can accumulate city by city, polluting entire regions.

In most of Canada's large cities, summer concentrations of low-level ozone occasionally exceed the maximum acceptable National Ambient Air Quality Objectives. In three regions of Canada, however, these concentrations regularly exceed acceptable levels during the summer months. These are the Lower Fraser Valley of British Columbia; the corridor between Windsor, Ontario, and Quebec City, Quebec; and the area surrounding Saint John, New Brunswick.

Ozone can be created locally and can also come from sources upwind. In British Columbia, the ozone is nearly all produced locally. In Southern Ontario and Quebec, the ozone created by local sources is supplemented by ozone from the Great Lakes states of the United States. In southeastern New Brunswick and Nova Scotia, nearly all the ozone moves in from the U.S. Atlantic seaboard, Quebec and Ontario. As mentioned, low-level ozone tends to break down into harmless components after a day or more, so shifting winds, variations in sunlight and other factors account for high pollution levels.

These three regions have been designated as "ozone non-attainment areas" by the Canadian Council of Ministers of the Environment. (Non-attainment areas do not meet Canada's National Ambient Air Quality Objectives.) The federal and provincial governments have targeted non-attainment areas for special control measures as part of a national $NO_x$/VOCs Management Plan (see Volume 2 for a description of current and announced control measures). In the decades ahead, if more action is not taken, additional regions of Canada could face similar problems.

## URBAN SPRAWL

Non-attainment areas are often areas where land use and development patterns, transportation, and pollution are intimately tied together. For example, urban sprawl causes increased fuel consumption and exacerbates environmental pollution problems.

Non-attainment areas often have the following characteristics:

- development is dense;
- urban development spreads to rural areas rather than becoming more concentrated;
- the single-family, lower density, suburban housing pattern is specifically designed around the car and encourages its use; and
- more public transportation is provided than in attainment areas, but public transportation services are concentrated much more in the urban core. For example, transit use is very high in Toronto (use, per capita, is the second highest in North America, after New York City), but outside the city core, cars move the people with some help from buses.

The urban sprawl pattern has disadvantages for public transportation carriers, who require high population densities along their routes in order to be efficient. In turn, lack of public transportation encourages car use, and this becomes the easiest and seemingly most natural choice for short to medium-distance intercity trips.

## GLOBAL WARMING

Although scientists continue to debate the effects of global warming, the Intergovernmental Panel on Climate Change has confirmed the existence of the phenomenon known as the greenhouse effect. The Panel agrees that human activities are creating increased atmospheric concentrations of greenhouse gases: carbon dioxide ($CO_2$), chlorofluorocarbons (CFCs), methane, and nitrogen oxides ($NO_x$). Transportation is a major source of $CO_2$ and CFCs.

*$CO_2$ emissions:* Transportation contributes about 25 percent of Canada's $CO_2$ emissions from non-natural sources, and these originate as by-products of the combustion of carbon-based fuels. Such emissions cannot be controlled by treating exhaust gases, but must be reduced through decreasing fuel consumption or using non-carbon energy sources such as solar energy and hydro-electric power or nuclear energy. Unlike the emissions that contribute to low-level ozone, $CO_2$ can last in the atmosphere for as long as 200 years. Therefore, the cycle of $CO_2$ increase and decrease is much longer, and its potential impact more persistent, than that of low-level ozone. Canada has adopted a goal of stabilizing total greenhouse gas emissions at 1990 levels by the year 2000. This requires a substantial reduction in $CO_2$ from the level that is anticipated if current trends continue unchecked.

*CFCs:* Transportation also adds CFCs to the atmosphere, primarily through leakage from vehicle air conditioners, which have recently contributed about 25 percent of total Canadian CFC emissions. CFCs play a major role in the destruction of the protective high-level ozone layer in the stratosphere (see Volume 2 for a summary of differences between high-level and low-level ozone). Canada is in the forefront of international action on CFCs, having made a commitment to eliminate CFCs by 1997. At present, manufacturers are starting to use other chemicals in car air conditioners.

The Canadian Climate Program Board predicts that, if global warming continues into the next century, Canada's climatic zones may shift northward and sea levels may rise; both effects would have economic and social consequences. Although scientific evidence is not clear regarding global warming, prudence suggests that efforts be made to further reduce fuel consumption. Such efforts can be successful. Despite an increase in traffic and the number of cars, total annual gasoline consumption in Canada today is lower than it was in 1975.

## ASSESSING ENVIRONMENTAL DAMAGE

Scientists find it extremely difficult to measure the effects of transportation on the environment. Use of land for transportation disrupts wildlife habitats, but ecologists cannot gauge the full effects of these changes. Chemicals in vehicle emissions affect people, plants, animals and buildings, but medical scientists, botanists, biologists and chemists cannot determine with accuracy the relationships between doses of chemicals and responses in sickness or damages. Global warming is changing our weather patterns, but atmospheric scientists are unable to predict how much warming to expect, how regional temperatures will change, and how these changes will affect growing seasons, rainfall and sea levels.

Canadians experience the effects of environmental damage from transportation in unequal ways. For example, those living close to major airports must live with noise pollution from airplanes, even though they may never travel by air; their properties are also cheaper for the same reason — noise. Similarly, people who live close to freeways and railway tracks must live with noise pollution and lower property values. Farmers and foresters who work far from urban areas must deal with the effects of foliage damage from air pollution created many kilometres away. Those who live outside cities often travel further to get to educational, vocational, cultural and commercial services than do people living near the centre of the city, yet it is the city-dwellers who must live with the resulting air pollution, noise, disruption from traffic, and inconvenience.

It is difficult to estimate the costs of environmental damage. In rare cases, it is possible to make a direct link between cause and effect, and then estimate the costs. For example, when crop values are diminished due to low-level ozone, a market price for the loss can be calculated.

Some researchers have asked individuals what they would pay in hypothetical situations for improvements in environmental conditions. Others have suggested that clean-up costs be used as a basis for estimating environmental damage. There are examples of public agencies' willingness to bill companies for the costs of treating chemical discharges into waterways. Unfortunately, this approach cannot be applied to all types of damage, particularly irreversible damage. What price can be charged for the loss of a species or in cases where cleanup options do not exist? How can a dollar figure be assigned to the damages caused by global warming? What value can be put on the social and psychological effects of environmental problems caused by transportation? Can a link be made between actions taken by travellers in one region and damage that occurs in another region?

Since researchers cannot advise governments, with certainty, on how much effort it will take to solve environmental problems, the amount of effort to expend remains a question of judgement. In other words, one must judge whether or not the damage reductions are worth the costs while being uncertain about both damage reductions and costs. The trade-offs between costs and damage reductions in current solutions may have to change as knowledge of environmental damage increases. As costs become more measurable, the basis for setting prices for environmental damage will improve.

It is therefore important that governments continue to study, monitor and set goals to reduce environmental damage at the local, provincial, territorial, national and international levels. In addition, more research funding should be directed toward the study of environmental damage effects and costs.

## CONTROLLING ENVIRONMENTAL DAMAGE

At present, there are three ways to reduce the environmental damage associated with transportation.

The first way is to reduce the amount of fuel emissions per unit of travel by improving the technology of vehicles — increasing engine efficiency, treating exhaust to trap or chemically eliminate pollutants, and reducing vehicle weight in order to lower fuel consumption.

The second way is to reduce the volume of traffic by encouraging travellers to switch from cars to public modes in situations where public modes are less environmentally damaging, to reduce the number of trips they take, or to shorten their trips.

The third way is to reduce the effects of damage with remedial clean-ups or by shielding those who are affected (with noise barriers, for example).

Controlling environmental damage is expensive. All three methods cost individuals either as travellers or as taxpayers. Individuals pay for environmental clean-up, motor-vehicle control equipment and its maintenance,[1] administering and enforcing environmental regulations, and subsidizing public modes of travel. Travellers also pay a cost in time and inconvenience if they change modes or types of travel, or relocate residences or places of work.

These costs are likely to increase if the controls on environmental damage become more stringent. The technology to improve fuel consumption or reduce engine emissions further may be very expensive.

Individuals and governments balance the benefits of travel against the costs of controlling environmental damage. Individuals do this when they make travel decisions, purchase vehicles and buy homes. Governments do this when they adopt measures to reduce environmental damage, thus supplementing and modifying individual decisions. Governments take measures such as these because they believe that:

- travellers, who create the environmental damage, do not adequately consider the damage to non-travellers when they make travel decisions;
- many individuals are unable to assess potential damage because of the scientific complexity and uncertainty associated with environmental causes and effects; and

- individual actions may not be extensive enough or coordinated enough to achieve the desired change.

## COORDINATION AND COOPERATION

All levels of government should coordinate their approaches to environmental issues. We support the adoption of explicit goals, such as the national goals for reductions in CFCs, $CO_2$, $NO_x$ and VOCs, for control of environmental damage. We believe, however, that current government decisions can be made more consistently and can achieve these goals at lower costs. We encourage governments to ensure that such goals are realistic, that all concerned are committed to the goals, and that the costs and effectiveness of measures taken to realize these goals are carefully and thoroughly examined.

Governments must be careful about when, where and how they apply environmental controls. For some problems, governments may have to look for regional or local solutions. This is particularly true for pollution problems that occur in specific locations or at certain times. For example, the concentration of carbon monoxide (CO) and diesel particulates is greatest in city centres when traffic is concentrated during windless conditions.

We are particularly concerned about low-level ozone damage in the Lower Fraser Valley in British Columbia, in the corridor between Windsor, Ontario, and Quebec City, Quebec and around Saint John, New Brunswick. As discussed earlier in this chapter, these three areas of Canada have concentrations of low-level ozone that regularly exceed acceptable levels during the summer. It may be costly and unfair to implement uniform national standards to ease this regional problem. The most cost-effective solutions may involve regional controls on vehicle use, travel restrictions at times of greatest damage, or controls on non-transportation sources. British Columbia recently addressed this issue by implementing annual vehicle emission control checks in the Greater Vancouver area. By forcing people to keep cars tuned-up, they are able to reduce emissions without adding special equipment.

Because these areas are especially vulnerable, we **recommend** that:

---

**7.1 Governments consider regional solutions to ozone non-attainment areas, including special regional regulations such as speed limits or periodic motor-vehicle emissions testing for all classes of vehicles, and higher emissions surcharges at times of the year when ozone is a problem.**

---

We recognize that it may not always be practical to administer and enforce a regional standard — for example, ensuring that all cars within a region are fitted with emissions-control equipment may be difficult. Governments must try to find a balance between obtaining low-level ozone reductions in target regions and imposing unnecessary costs on travellers outside those regions.

For other problems, the strategy for environmental controls must be as broad as possible, encompassing all sources throughout the country, and the world, and extending across all sectors. The potential damage from global warming brought about by $CO_2$ emissions cannot be solved only by local fuel conservation programs. It is a global problem, and all sources of $CO_2$ must be examined to find the most efficient and effective ways to reduce these emissions. We believe that the passenger transportation sector should do its part but not be penalized more than other sectors that also produce $CO_2$. Governments should examine which controls can be applied at the lowest cost for the greatest benefit.

An international strategy to control global warming is being developed under the United Nations Convention on Climate Change, signed by some 150 countries at the Rio Conference in June 1992. Canada's national goal to stabilize $CO_2$ emissions at 1990 levels by 2000 is more stringent than the commitment required so far under that convention.[2]

We therefore **recommend** that:

---

**7.2 Canada continue to strive for development of an effective international strategy to control global warming, and seek to harmonize domestic policies and taxes with those of the international community.**

---

## PROTECTING THE ENVIRONMENT THROUGH REGULATION AND EDUCATION

In Canada, regulation and education play important roles in reducing environmental damage caused by transportation. Provincial and municipal governments have combined environmental objectives with those of urban and transportation planning. They regulate driving behaviour through traffic restrictions and parking controls, and run campaigns to persuade people to change modes or travel less.

The regulatory approach of the federal government includes controls on vehicle technology — primarily through setting motor-vehicle emissions standards, and obtaining voluntary agreements for improvements — particularly to meet fuel-consumption targets. The federal government also undertakes information campaigns to persuade travellers to change their travel behaviour.

This regulatory approach contributes substantially to lowering emissions. Regulators, however, often concentrate on what is easiest to administer and enforce, rather than on reducing damage for the lowest cost. For example, federal regulation focusses on motor-vehicle emissions, and, in particular, on passenger car emissions. As a result, pollution control is stricter for motor vehicles than for non-vehicular sources.

Governments, however, must be cautious when using a regulatory approach to reduce pollutants. While federal regulatory control of car emissions has been successful, governments should pay equal attention to emissions from other transportation vehicles such as buses, trucks, trains, airplanes and ferries.

Therefore, we **recommend** that:

---

**7.3 Governments continue to improve and apply regulations for effective control of environmentally damaging emissions. In doing so, they should ensure that:**

**(a) regulations be set so as to impose similar obligations (in terms of costs per unit of abatement) on each mode in a cost-effective manner;**

**(b) non-transportation sources of pollutants be treated similarly to those in transportation; and**

**(c) the costs of deciding, implementing and administering transportation regulations be paid for by the users of the transportation system.**

---

Although urban transportation is beyond our mandate, we believe that Canadians should choose where they want to live on the condition that they pay the full cost of those choices. We note that if, as a result of Canadians facing the full costs of their choices, urban land-use patterns were to change, different travel behaviour might follow. For example, if development in a region were dense and consisted of mixed commercial and residential properties — unlike urban sprawl development — the following would likely occur:

- home-to-work trips would be far shorter, encouraging other means of commuting including walking and bicycling;
- densities would be higher making public transportation more viable;

- land values would be higher and parking scarcer and more expensive, discouraging car use and ownership; and
- the mix of residential and commercial establishments would encourage doing errands by means other than the car.

Reduced levels of car use would also lead to a greater use of any available public transportation for intercity trips. This would result in lower levels of emissions per capita.

## PROTECTING THE ENVIRONMENT THROUGH PRICING

While regulations will continue to play a significant role in protecting the environment from pollution caused by travel, we do not believe that regulation alone will be sufficient. Regulations should be supplemented by charges to travellers, which provide an efficient way of encouraging travel behaviour that will limit damage to the environment. When travellers pay for the damages they inflict on the environment, they will make choices and may change their travel behaviour.[3] Some will travel less to save money. Others will switch to modes that are cheaper because of lower environmental charges. Still others will choose to pay the higher price to travel on the less environmentally friendly mode. Owners of transportation equipment and infrastructure will change their equipment or otherwise adjust to decrease the pollution they cause in order to reduce the environmental costs they have to pay, and, therefore, have to charge.

In addition, environmental charges will encourage transportation providers to conserve fuel or switch to less-polluting fuels. In all cases, travellers would choose their own mix of solutions at the least cost to themselves, but would take into account the damage they impose on the environment.

How should travellers be charged for the damage they inflict on the environment? Like many other aspects of passenger transportation, the issues are complex and the solutions are not easy. It is impossible to estimate the costs of all environmental damage precisely, and therefore to charge travellers accurately for all the damage they cause.

It may be possible, with future technology, to charge passengers directly for the emissions of air pollutants and noise created by their vehicles. This may be done either through monitoring vehicles continuously or through monitoring the distances travelled and combining this with an emissions rating for particular vehicles. The technology to measure vehicle emissions and noise, however, is not yet in general use.

Emissions charges could be what is required to meet Canada's national goals for the environment. We suggest that a practical means of determining prices for emissions charges would be to estimate the charges required to meet Canada's national goals for reducing $CO_2$, $NO_x$ and VOCs. When dealing with emissions charges, it is imperative that the following recommendation be read in conjunction with what we say in Chapter 17 on environmental charges based on global damages and their implications for international competition.

We believe that, for the immediate future, emissions surcharges should be placed on fuel sales.[4] Such emissions surcharges are presently the best and fairest means of charging passenger transportation users for the environmental damage they cause. If imposed at the same rate per unit of emissions from all sources, these surcharges would affect all modes and all fuel sources equally and would be fair. For $NO_x$ and VOCs emissions, the surcharges would apply only in the ozone-sensitive regions, and only during those summer months when ozone levels are damaging. An alternative solution for $NO_x$ and VOCs in sensitive regions might be vehicle registration fees based on estimated annual emissions from the specific vehicle.

We therefore **recommend** that:

---

**7.4 Users of transportation pay for the environmental consequences of their actions, such as:**

**(a) actual government costs for creating policies and regulations to prevent damage;**

**(b) environmental clean-up costs or mitigation (e.g. noise abatement);**

**(c) compensation for those affected by environmental damage, where this can be determined; and**

**(d) best estimate of damage where costs cannot be compensated because it is not possible to accurately identify individually those who are affected by environmental damage or the extent to which they have been affected.**

In some cases, estimates of the cost may not be available, but governments may continue to judge it prudent to set goals for pollution control, presumably guided by the social costs of the environmental damage in question. Such goals provide an alternative basis for establishing levels of charges.

We therefore **recommend** that:

**7.5 Where environmental goals have been established in the absence of reliable information on damage costs, charges and/or changes in regulations be set at the levels expected to induce the behavioural change that will meet the goals.**

**7.6 Environmental emission charges be applied equally to all modes of transportation and to non-transportation sources, on as close to a per-unit-of-emission basis as practical.**

We further **recommend** that:

---

**7.7 Government clearly separate the revenue that comes from emissions charges from the revenue that comes from other passenger transportation charges, and ensure that:**

**(a) revenues raised from emissions charges be first used to clean up environmental damage from transportation and to compensate those affected, if they can be identified;**

**(b) remaining revenues be used to lower general tax rates; and**

**(c) revenues from emissions charges not be used for transportation system expansion or maintenance.**

---

For example, compensation could take the form of screens around transportation structures to reduce noise levels or the provision of a safe means of crossing highways or railways. We also believe that it would be fair to use the funds to provide improved public transport in the inner city, where residents are affected disproportionately from traffic caused, in large part, by those living in the suburbs. Such funds could be used for research into pollution prevention and for education on protecting the environment.

Although urban and freight transportation are beyond our mandate, we believe that these principles of cost-effective regulations and emissions charges should be adopted in urban and freight transportation planning and in other sectors of the economy.

## COMPARISON OF POTENTIAL EMISSION CHARGES BY MODE

For the purposes of illustration, we obtained estimates of emissions for the different modes and calculated the surcharges that might be required to meet Canadian government objectives of reducing $CO_2$ to 1990 levels in the year 2000, and reducing $NO_x$ and VOCs in non-attainment areas in summer. Cars, airplanes, buses and trains emit different amounts of the gases that contribute to air pollution and global warming. Table 7-1 and Chart 7-1 show emissions per passenger-kilometre on two sample intercity routes, a short trip from Toronto to Montreal and a longer trip from Saskatoon to Halifax, for the four passenger modes.

*Table 7-1*

*EXAMPLES OF EMISSIONS BY MODE ON TWO INTERCITY ROUTES*

| EMISSIONS PER PASSENGER-KILOMETRE IN GRAMS, 1989 — TORONTO TO MONTREAL | | | | | | | |
|---|---|---|---|---|---|---|---|
| **Type of emission** | | **Public transportation with current occupancy rates**[a] | | | **Public transportation with all seats filled** | | |
| | Car | Bus | Train | Airplane | Bus | Train | Airplane |
| CO | 5.20 | 0.18 | 0.34 | 0.17 | 0.14 | 0.21 | 0.11 |
| VOCs | 0.94 | 0.05 | 0.14 | 0.10 | 0.04 | 0.09 | 0.07 |
| $NO_x$ | 0.75 | 0.40 | 1.54 | 0.34 | 0.31 | 0.96 | 0.23 |
| $CO_2$ | 128 | 30 | 76 | 220 | 23 | 47 | 148 |

| EMISSIONS PER PASSENGER-KILOMETRE IN GRAMS, 1989 — SASKATOON TO HALIFAX | | | | | | | |
|---|---|---|---|---|---|---|---|
| **Type of emission** | | **Public transportation with current occupancy rates**[b] | | | **Public transportation with all seats filled** | | |
| | Car | Bus | Train | Airplane | Bus | Train | Airplane |
| CO | 5.20 | 0.24 | 0.77 | 0.13 | 0.14 | 0.54 | 0.09 |
| VOCs | 0.94 | 0.07 | 0.32 | 0.08 | 0.04 | 0.23 | 0.05 |
| $NO_x$ | 0.75 | 0.54 | 3.52 | 0.26 | 0.31 | 2.46 | 0.17 |
| $CO_2$ | 128 | 41 | 173 | 167 | 23 | 121 | 113 |

**Sources:** **VHB Research and Consulting Inc., "Environmental Damage from Transportation," Volume 4 of this report, and Royal Commission staff estimates.**

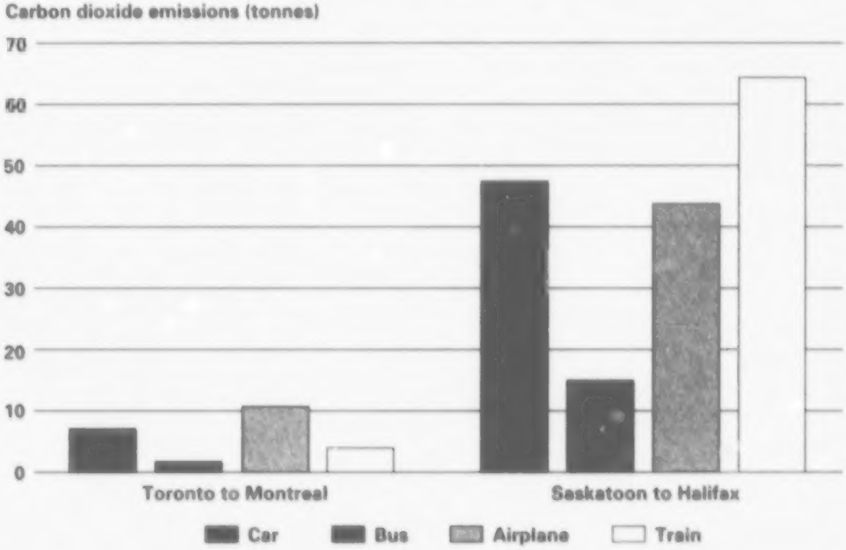
**a.** **Rates at which seats are currently occupied on public transport vehicles are estimated for the Toronto to Montreal route at 77 percent for bus, 62 percent for train and 67.5 percent for airplane. For cars, the occupancy rate is 1.8.**

**b.** **On the Saskatoon to Halifax route, the estimated occupancy rates are 57 percent for bus, 70 percent for train and 67.5 percent for airplane.**

**Note:** **Only direct emissions are included, arising from the trip alone, with no inclusion of indirect emissions from equipment and infrastructure construction. All emissions calculations are based on current vehicles and equipment. If vehicles such as cars and trains were powered by electricity, emissions would depend on the source of electric power.**

*Chart 7-1*

*CARBON DIOXIDE EMISSIONS PER 100 PERSON-TRIPS, BY MODE, TORONTO TO MONTREAL AND SASKATOON TO HALIFAX*



Sources: VHB Research and Consulting Inc., "Environmental Damage from Transportation," Volume 4 of this report, and Royal Commission staff estimates.

Note: Only "direct" emissions are included, arising from the trip alone, with no inclusion of "indirect" emissions from equipment and facilities construction.

Table 7-1 shows that:

- on the shorter Toronto to Montreal trip, airplanes have the lowest emission of CO and $NO_x$, while buses have the lowest emission of VOCs;
- for both long and short trips, buses have the lowest fuel consumption and, therefore, the lowest $CO_2$ emissions;
- on the longer Saskatoon to Halifax trip, airplane emissions are lower per passenger-kilometre than on the shorter trip, while those of buses are higher due to lower occupancy and those of trains are higher due to the use of sleeping cars; and

- current-technology trains have higher emissions of $NO_x$ than any of the other modes, and this would remain the case even if all train seats could be filled.

Tables 7-2 and 7-3 illustrate potential emissions charges and how they might differ by mode for the two trips, Toronto to Montreal and Saskatoon to Halifax. These sample routes are representative of all the types and lengths of trips taken on the transportation system.

We caution readers to be aware that the results shown in Tables 7-2 and 7-3 are extremely speculative. While the federal government has adopted national goals for global warming protection and for ozone control, a method for achieving them through emissions charges has not been designed thoroughly. Governments would have to set charges carefully to induce the appropriate responses by travellers. For our illustration, we have calculated the surcharges on the basis of the government pursuing its announced national goals, relying mostly on charging instead of additional regulation of emissions. As a result, our example charges are high.

For purposes of this illustration, we used a $CO_2$ charge based on $120 per tonne of carbon, which becomes $32.70 per tonne of $CO_2$ emissions, or 7.7¢ per litre of gasoline. This charge would apply everywhere, and year-round. For $NO_x$ and VOCs, we made the assumption that charges would be imposed only in the ozone non-attainment areas, which include the whole of the Toronto to Montreal trip, but only a small portion of the Saskatoon to Halifax trip. The $NO_x$ and VOCs charges should also be applied only during those periods when ozone levels become unacceptably high. We have assumed that, in order to be practical, the charges would need to be applied uniformly throughout the summer months (probably May through August). The illustrative charges in Tables 7-2 and 7-3, therefore, are different for winter and summer.

*Table 7-2*

### ILLUSTRATIVE EMISSIONS CHARGES, IN DOLLARS PER PERSON-TRIP, TORONTO TO MONTREAL

| | **Winter** | **Summer** | | |
|---|---|---|---|---|
| **Carrier** | **$CO_2$ charge ($)** | **$CO_2$ charge ($)** | **$NO_x$/VOCs charge ($)** | **Total ($)** |
| Car | 2.20 | 2.20 | 4.60 | 6.80 |
| Bus | 0.50 | 0.50 | 1.20 | 1.70 |
| Train | 1.30 | 1.30 | 4.50 | 5.80 |
| Airplane | 3.50 | 3.50 | 0.80 | 4.30 |

**Notes:** For this trip, we have assumed the following:

- Toronto to Montreal emissions per passenger-kilometre are as estimated for Table 7-1, based on emissions by current vehicles at current average occupancies (the actual surcharge would vary with the fuel consumption and the occupancy rate of the particular vehicle);
- CO and particulate emissions are not priced for intercity trips, as their damage is urban;
- All levels of government declare it necessary to control ozone by reducing summertime emissions of VOCs and $NO_x$ in this non-attainment area beyond the reductions scheduled in the $NO_x$/VOCs Management Plan, and to a level that they can forecast will be met if a charge of $5,000 per tonne is levied, on all sources in the region; and
- $CO_2$ is charged for separately at a rate of $33 per tonne, or $120 per tonne of carbon, an amount that, if applied to all sectors in Canada, is predicted to achieve stabilization at 1990 levels in 2000.

The above are illustrative estimates of charges that would be associated with existing services. These charges would be lower if emissions were reduced through improved technology. In particular, as discussed in the text below, if trains powered by electricity were used, the charges applicable to trains could be very low (or nil) if the electric power were generated mainly (or entirely) from non-fossil-fuel sources.

The figures for the Toronto to Montreal trip show that:

- year-round charges for $CO_2$ would be lowest for bus passengers and highest for air passengers;
- summer charges for $NO_x$ and VOCs would be lowest per passenger-trip for bus passengers and highest for car passengers;
- total summer charges at the assumed levels would be lowest for bus and highest for car;

- charges would not be large when compared with fares for the public modes;
- the winter charge for $CO_2$ emissions of $2.20 for a car traveller would amount to $3.80 per car (with about 1.7 occupants on average), or 7.5¢ per litre of gas if charged through a gasoline tax. The summer charge of $6.80 for a car traveller would amount to $11.80 per car, or about 23¢ per litre of gas;[5] and
- the summer charge for a car traveller would be only about $1.00 higher than that for a train passenger on this trip.

We recognize that environmental arguments are advanced in favour of introducing conventional or high-speed trains powered by electricity on this route. We obtained estimates of the possible electricity consumption of such trains and considered possible sources of that electricity. To the extent that the electricity could be supplied from hydro-electric plants or nuclear generating stations, trains would produce none of the $CO_2$ or air pollutants created by the other modes. For a high-speed train, if the electricity were generated from fossil-fuelled power stations, it would produce per passenger-kilometre about 64 grams of $CO_2$, 0.3 grams of $NO_x$ and 0.8 grams of sulphur dioxide.[6] Using our illustrative charges, this worst case would create an environmental charge of about $3.60 per passenger-trip in winter and $4.50 in summer.[7] More reasonably, if the electricity was provided from fossil-fuelled plants in proportion to their forecast contribution to the Ontario and Quebec electricity grids in 2000, the surcharge indicated would be only about one tenth of these levels — that is, only about 40¢ per passenger-trip. For an electrified conventional train, power requirements per passenger-kilometre would be even lower, and emission surcharges correspondingly less.

Electrified trains would thus, on average, produce lower environmental costs than any other mode. However, this cost advantage would not be large as a portion of total trip costs. Furthermore, the estimates are only of damage from $CO_2$ and air pollutants, ignoring other environmental damage from hydro-electric and nuclear stations.

*Table 7-3*

ILLUSTRATIVE EMISSIONS CHARGES, IN DOLLARS PER PERSON-TRIP, SASKATOON TO HALIFAX

| | Winter | Summer | | |
|---|---|---|---|---|
| **Carrier** | **$CO_2$ charge ($)** | **$CO_2$ charge ($)** | **$NO_x$/VOCs charge ($)** | **Total ($)** |
| Car | 19 | 19 | 5 | 24 |
| Bus | 6 | 6 | 2 | 8 |
| Train | 25 | 25 | 8 | 33 |
| Airplane | 19 | 19 | 1 | 20 |

**Note:** **The emission factors per unit of fuel consumed are assumed to be the same as in the Toronto to Montreal case, but fuel consumed per passenger differs through different load factors and types of equipment. It is also assumed that the charge per tonne of $NO_x$ and VOCs would only be imposed within the part of the trip through designated ozone-sensitive areas. Other assumptions are the same as for the Toronto to Montreal trip.**

The figures for the Saskatoon to Halifax trip show that:

- $CO_2$ charges would be lowest for bus passengers and highest for train passengers;
- $NO_x$ and VOCs charges would be small relative to $CO_2$ charges, as most of the trip would be outside the ozone non-attainment areas; and
- charges in winter and summer would be lowest for bus passengers and highest for train passengers.

Although transportation will continue to contribute to environmental damage, our recommendations will limit this damage. Implementing regional solutions to ozone non-attainment areas, developing an international strategy on global warming, improving regulations on emissions control and charging fairly for environmental damage will all contribute to protecting Canada's environment.

# ENDNOTES

1. The costs of vehicle-emissions controls are estimated to be about $500 per vehicle, or 0.5¢ per vehicle-kilometre annualized over an average vehicle-lifetime of about 160,000 kilometres.

2. The Convention's objective reads in part (Article 2):

   "The ultimate objective . . . is to achieve . . . stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner."

   Its "commitments" in Article 4 include:

   "Each of the developed country parties shall adopt national policies and take corresponding measures on the mitigation of climate change, by limiting its anthropogenic emissions of greenhouse gases and protecting and enhancing its greenhouse gas sinks and reservoirs. These policies and measures will demonstrate that developed countries are taking the lead in modifying longer-term trends in anthropogenic emissions consistent with the objectives of the Convention, recognizing that the return by the end of the present decade to earlier levels of anthropogenic emissions and other greenhouse gases . . . "would contribute to such modification . . . ." and

   "In order to promote progress to this end, each of these Parties shall communicate, within six months of entry into force of the Convention for it and periodically thereafter . . . detailed information on its policies and measures . . . as well as on its resulting projected anthropogenic emissions . . . with the aim of reducing individually or jointly to their 1990 levels these anthropogenic emissions of carbon dioxide and other greenhouse gases. . . ."

   United Nation's Framework Convention on Climate Change, New York, May 15, 1992.

3. Research has proven that collective reactions to gasoline prices are like the reactions for most goods: as the price goes up, the amount bought goes down. In the short term, it does not go down much: a 10 percent price increase might bring only a 2 percent reduction in sales; but over the long term — maybe a few years — the reduction is much larger, perhaps of the order of 8 percent.

   This research might seem contrary to experience. Prices have been continuously rising, but sales don't seem to be falling. This is because we are referring to real increases in prices, that is, in addition to general inflation, and to sales reductions as compared with the level of sales that would have occurred otherwise. When prices are changing routinely because of inflation, and growth in population and vehicle ownership is causing continuous increases in gasoline sales, it is not easy to recognize real price increases and the gradual reduction in sales they produce. But we are confident that the relationships will hold, and that if pollution charges are added to real gasoline prices, sales will be lower.

   Researchers cannot definitively explain the difference between the short-term and long-term effects of price increases, but they suggest that, in the short term, people are locked in patterns of business and social activities. They cannot adjust easily to price increases by driving less or immediately purchasing a different car. Over the longer term, however, when their car comes up for renewal they can replace it with one that is more fuel efficient, and they can change houses or jobs to alter their patterns of car use. They may or may not be aware that they are weighing the price of gas in all these decisions.

4. This would work most effectively for $CO_2$ because its emission rate per unit of fuel is constant. Charging for other air pollutants through fuel-price surcharges would be a less efficient way of changing people's behaviour. This is because the charges could not be tailored to each vehicle's actual emissions, but would have to be averaged for the entire class of vehicles using a particular fuel type — that is, gasoline-fuelled motor vehicles, diesel-fuelled motor vehicles, trains and jet aircraft.

   Such charges could not be reduced by a traveller's or carrier's actions to lower the amount of emissions per unit of fuel, though charges could still be reduced by limiting vehicle use. They would essentially constitute another incentive to reduce fuel consumption.

5. We remind the reader that if our recommendations were implemented in their totality, the result would be a more efficient passenger transportation system, and that while the cost to some travellers would go up, the overall cost to Canadians would be lower. We also caution the reader that this price increase is for gas used only in non-attainment regions in summer.

6. Estimates for a 300 km/hr service, with 75 percent load factor, requiring about 0.10 kilowatt hours per passenger-kilometre.

7. This includes a cost of $6,000 per tonne of sulphur dioxide, derived from the report to the Royal Commission by VHB Research and Consulting Inc., cited in Table 7-1.

# CHAPTER 8

# IMPROVING SAFETY

## INTRODUCTION

Airplane, bus, train and ferry accidents often command eye-catching headlines, but in reality, public transportation is much safer than private transportation. During 1990, 103 Canadians died as a result of an air, train or ferry accident, while 3,957 travellers died and 263,000 were injured in road accidents.[1]

We studied the safety of different modes of travel, and the health and damage costs of accidents. We found, overall, that the safety of our transportation system is improving. The number of accidental deaths from all transportation was lower in 1990 than it was in any year since 1962. Nevertheless, transportation accidents of all kinds cause grief and suffering for many Canadians and are a substantial burden on our society in health and damage costs.

Our principle — that travellers should pay the costs of transportation — means that they should also pay the costs of accidents that are associated with their mode of travel. We have therefore examined safety and accident costs by mode, and who pays for the cost of accidents, safety measures and programs.[2]

## INTERCITY PASSENGER TRANSPORTATION SAFETY

We measured safety by comparing fatalities for each mode relative to passenger-kilometres of travel. We limited our measure to fatalities because comprehensive data on injuries are available only for road vehicles.

Two different measures of safety in passenger transportation are used in this chapter:

- passenger fatality rate: the number of passengers killed per billion passenger-kilometres; and
- fatality rate in passenger operations: the number of persons killed per billion passenger-kilometres, including passengers, crew and others such as bystanders, cyclists and occupants of other vehicles.

## AIRPLANE SAFETY

How safe is commercial aviation? Commercial air travel in Canada is organized into three categories of carriers based primarily on the number of passengers carried annually:[3]

- Level 1 carriers each transport more than one million passengers annually;[4]
- Level 2 carriers each transport 50,000 to one million passengers annually;[5] and
- Levels 3 to 6 carriers include all other small commercial operations.[6]

*Table 8-1*

*FATALITIES DUE TO COMMERCIAL AIRPLANE ACCIDENTS, 1981–1990*

| Level of carrier | Number killed |
|---|---|
| Levels 1 and 2 | 68<br>(57 passengers, 11 crew) |
| Levels 3 to 6 | 539<br>(270 passengers, 269 crew) |
| **Total** | **607** |

**Source: Transportation Safety Board of Canada.**

From 1981 to 1990, 607 people died in accidents involving Canadian-owned commercial air carriers. The figures for levels 1 and 2 carriers in Table 8-1 include single accidents at Cincinnati, Ohio, in 1983[7] and Dryden, Ontario, in 1989 that dramatically raised the fatality rate in the years those accidents occurred. Such accidents make it difficult to calculate fatality rates that indicate trends in aviation safety. Nevertheless, to identify the risks to air travellers in recent years, we averaged total fatalities relative to the number of passenger-kilometres travelled over the decade (Table 8-2).

*Table 8-2*

*COMMERCIAL AIRPLANE FATALITIES PER BILLION PASSENGER-KILOMETRES, 1981–1990*

| **Level of carrier** | **Percentage of passenger-kilometres flown by all commercial carriers** | **Passenger fatality rate (passenger deaths only) per billion km** | **Fatality rate in passenger operations (passenger and crew deaths) per billion km** |
|---|---|---|---|
| Level 1 | 88.0 | 0.05 | 0.05 |
| Level 2 | 8.5 | 0.7 | 1.0 |
| Levels 1 and 2 | 96.5 | 0.11 | 0.13 |
| Levels 3 to 6[a] | 3.5 | 14.0 | 28.0 |

**Sources: Fatalities are from Transportation Safety Board of Canada. Passenger-kilometres are from Statistics Canada, Catalogue No. 51-002 and 51-006.**

**[a] Passenger-kilometres are available only for levels 3 and 4 carriers, but passenger traffic carried by levels 5 and 6 operators is likely so small that it would not affect these rounded fatality rates.**

The figures in Table 8-2 show that:

- Level 1 carriers had a passenger fatality rate equivalent to one death in every 20 billion passenger-kilometres;[8]
- Levels 1 and 2 carriers had a passenger fatality rate equivalent to one death every 9 billion passenger-kilometres; and
- Levels 3 to 6 carriers had the largest passenger fatality rate, equivalent to one death every 0.07 billion passenger-kilometres.

While fatality rates for all commercial aviation fell between 1981 and 1990, the observed improvement in safety was among smaller carriers. Accidents involving levels 1 and 2 carriers are so rare and vary so much from year to year that it is impossible to determine whether or not the carriers' safety improved during this decade. Nevertheless, it is clear that levels 1 and 2 carriers remain much safer than levels 3 to 6 carriers.

From 1981 to 1990, 556 people died in accidents involving private airplanes. There are no figures for passenger-kilometres flown for private aviation. The only indicator of annual activity is the total number of hours flown for all private aircraft regardless of the number of passengers. This figure reveals that private flying has declined during the last decade. The number of fatal accidents per year also appears to have fallen, but the figures are so variable that it is not possible to establish any trends in the accident rates during the decade.

Risks in private flying can be compared with those of commercial aviation, using average rates of fatal accidents per million flying hours. As Table 8-3 shows, there were 33 accidents per million hours of private flying and only 1 accident per million hours for levels 1 and 2 carriers.

*Table 8-3*

*NUMBER OF FATAL ACCIDENTS PER MILLION FLYING HOURS,[a] 1981–1990*

| Type of carrier | Number killed per million flying hours |
|---|---|
| Private flying | 33.0 |
| Levels 1 and 2 carriers | 0.9 |
| Levels 3 to 6 carriers | 17.0 |

**Source: Transportation Safety Board of Canada.**

[a] **This ratio is a customary measure in the aviation industry of airframe and engine performance, but note that it refers to the number of accidents (crashes) in which deaths occurred, rather than the number of people killed, used otherwise throughout this chapter. This is believed to be appropriate as no measure of passenger activity is available for private flying.**

No official statistics exist for fatality rates per passenger-kilometres for private aircraft, and no distinction can be made between their use for transportation and recreation. However, based on the number of flying hours, the fatality rate for private aircraft appears to be much greater than the 20 deaths per billion passenger-kilometres for cars.[9]

Has airline deregulation affected commercial air carrier safety? Airline deregulation — the removal or relaxation of economic regulation of airline operations, such as easing entry to markets and removing price constraints — began in Canada in 1984. Regulation of airline safety, however, remained and has been strengthened since then. To date, there is no evidence that economic deregulation has affected airline safety. We note, though, that it takes a substantial period of time (a decade or more) to identify changes in safety trends, because accidents involving larger carriers are so rare.

Since we did not have sufficient statistics to determine with confidence how airline deregulation has affected Canadian air carrier safety, we turned to research in the United States, where economic deregulation began in 1978, six years before it was introduced in Canada. U.S. research suggests that deregulation in that country has not affected airline safety, and that accident rates continue to follow the downward trend established before deregulation.[10] Furthermore, the increase in air travel, which resulted partly from travellers flying instead of driving, substantially reduced the number of trips by car (a more dangerous mode) and improved overall safety.[11]

## TRAIN SAFETY

We found it difficult to determine any meaningful trends in fatalities per passenger-kilometre for intercity passenger trains. Deaths in collisions and derailments are too rare to determine accurately the safety trends for short periods. For example, there were no passenger deaths in eight of the years from 1981 to 1990. In 1986, however, there were 16 passenger deaths and 8 crew deaths in the Hinton, Alberta, crash (Table 8-4).

*Table 8-4*

*TRAIN FATALITIES PER BILLION PASSENGER-KILOMETRES, 1981–1990*

| Passenger fatality rate (passenger deaths only) | Fatality rate in passenger operations (deaths of passengers, crews and others)[a] |
|---|---|
| 0.8 | 13.8 |

**Sources: Fatalities are from Transportation Safety Board of Canada. Passenger-kilometres are from Statistics Canada, Catalogue No. 52-003 and 52-215, and unpublished data.**

**a. 175 people died in rail-grade crossing accidents, usually in motor vehicles, and 133 were killed trespassing on rail property. Many trespassing deaths may have been suicides, but the Transportation Safety Board's statistics do not distinguish them.**

## BUS SAFETY

Statistics describing the safety of intercity bus operations are scarce. Only five provinces — Saskatchewan, Manitoba, Ontario, Nova Scotia and Newfoundland — have recorded intercity bus accidents separately from those of city transit buses.

Table 8-5 presents data from these five provinces, but the available information does not cover the decade from 1981 to 1990 — only the three years from 1985 to 1987. Clearly, these data do not provide a sufficient basis to identify any long-term trends.

*Table 8-5*

*FATALITIES AND INJURIES INVOLVING INTERCITY BUSES, 1985–1987*

*(SASKATCHEWAN, MANITOBA, ONTARIO, NOVA SCOTIA, NEWFOUNDLAND)*

| | Passenger | Driver | Others[a] | Total |
|---|---|---|---|---|
| Deaths | 0 | 0 | 7 | 7 |
| Injuries | 73 | 27 | 165 | 265[b] |

**Source: Transport Canada special tabulation.**

**a. Primarily drivers and passengers in cars and light trucks that collided with buses.**

**b. Only 4 of the bus occupants and 17 of the other victims were injured severely enough to require hospitalization.**

We could not obtain the number of passenger-kilometres travelled by bus for the five provinces and, therefore, could not accurately determine the rates of death and injury per vehicle-kilometre and passenger-kilometre. Based on data for the number of bus trips and kilometres travelled throughout the entire bus industry, we have estimated an average fatality rate for this three-year period. From 1985 to 1987, there were roughly two deaths per billion passenger-kilometres for all victims, whether passengers, drivers or others. Although there were no passenger deaths in the five provinces from 1985 to 1987, bus crashes can cause passenger fatalities.[12]

We have made a rough estimate of bus safety in order to compare it with the other modes: across the whole country and over a longer period of time, the true number of fatalities from travelling by bus could be placed between 0 and 50 percent of all bus-related deaths. This results in a passenger fatality rate of 0.0 to 1.0 deaths per billion passenger-kilometres (Table 8-6).

*Table 8-6*

*ESTIMATED INTERCITY BUS FATALITIES PER BILLION PASSENGER-KILOMETRES, 1985–1987*

| Passenger fatality rate[a] (passenger deaths only) | Fatality rate in passenger operations (deaths of passengers, crew and others) |
|---|---|
| 0.0–1.0 | 2.0 |

**Source: Passenger-kilometres are from Royal Commission staff estimates.**

**a. Not calculated from actual fatalities, but estimated as noted in the text.**

The majority of victims of bus accidents are not the bus passengers but the drivers and passengers of cars and light trucks involved in the accidents. Improvements to cars and light trucks and seat-belt use have assisted occupants of those vehicles to avoid and survive crashes. As cars and light trucks continue to become safer, travel by intercity bus will be safer primarily for others, but also for bus passengers.

## FERRY SAFETY

There were only six passenger deaths on ferries from 1981 to 1990, four of which were suicides. Crew deaths were even more rare. In all ferry operations, crew deaths averaged one third of the number of passenger deaths.

The annual numbers of fatalities on ferries are much too small and variable for trends to be recognized, or risks to be computed with confidence. Combining the average fatalities per year during the decade with the estimated traffic of 850 million passenger-kilometres in 1988, we were able to estimate the risks. Excluding suicides, the fatality rate in ferry operations (in crew, as well as passengers) was about 0.5 deaths per billion passenger-kilometres. The passenger fatality rate was 0.2 deaths per billion passenger-kilometres (Table 8-7).

*Table 8-7*

*Ferry Fatalities per Billion Passenger-Kilometres, 1981–1990*

| Passenger fatality rate (passenger deaths only) | Fatality rate in passenger operations (deaths of passengers and crew) |
|---|---|
| 0.2 | 0.5 |

**Sources:** Fatalities are from Transportation Safety Board of Canada. Passenger-kilometres are from carrier annual reports and Royal Commission staff estimates.

## CAR SAFETY

People driving private cars, vans and light trucks account for around 80 percent of intercity travel and 98 percent of the deaths related to intercity travel. Based on available data, we have calculated the passenger fatality rate and the fatality rate in passenger operations for 1989 (Table 8-8).

Table 8-8

CAR FATALITIES PER BILLION PASSENGER-KILOMETRES, 1989

| Passenger fatality rate (drivers and passengers) | Fatality rate in passenger operations |
|---|---|
| 10.0 | 13.0 |

Sources: Highway car fatalities are from Transport Canada. Passenger-kilometres are from Royal Commission staff estimates.

While the high rate of fatalities from road accidents concerns us, there are positive trends in road safety. The growth in fatalities has been much less than the growth in traffic. Although there are 14 times as many cars on the roads today as there were in 1930, the number of road deaths has only tripled. Improvement has been especially rapid in the past 20 years. Since 1973, the risk of death from car use has fallen faster than traffic has grown. The result is that the number of people killed has decreased annually.

## COMPARISON OF SAFETY BY MODE

Table 8-9 illustrates the passenger fatality rate and the fatality rate in passenger operations for all modes.

Table 8-9

ESTIMATES OF RECENT[a] INTERCITY FATALITY RATES BY MODE (PER BILLION PASSENGER-KILOMETRES)

| Mode | Passenger fatality rate[b] | Fatality rate in passenger operations[c] |
|---|---|---|
| Air — Level 1 carriers[d] | 0.05 | 0.05 |
| Air — Level 2 carriers[d] | 0.7 | 1.0 |
| Air — Levels 3 to 6 carriers[d] | 14.0 | 28.0 |
| Train | 0.8 | 13.8 |
| Bus | 0.0–1.0 | 2.0 |
| Ferry | 0.2 | 0.5 |
| Car | 10.0 | 13.0 |

Sources: Tables 8-2, 8-4, 8-6, 8-7 and 8-8.

a. Based on the 1980s as a whole or recent years in 1980s; see text and source tables.
b. Includes only passengers killed.
c. Includes passengers, crew and bystanders killed during passenger operations.
d. Includes all Canadian-registered carrier operations, domestic and international.

The figures show that:

- It is safer to travel on Level 1 air carriers than on any other mode.
- Cars cause about 12 times as many passenger deaths over the same distance as trains; at a minimum, 10 times as many deaths as intercity buses that operate on the same road system; and about 90 times as many deaths as levels 1 and 2 air carriers combined.
- Travel using major airlines, buses, trains or ferries is safer than travel by private car or private airplane. Private flying is probably much more dangerous than intercity car travel.

Table 8-9 includes only system-wide averages. The risks of travel also depend on the type of trip and its length. When governments contemplate transportation investment, they should take into account these system-wide safety rates, and should recognize that other factors, such as type of trip, can affect the contribution to safety of individual projects. We believe that traffic on intercity routes would, on average, be safer if some travellers switched from travelling by car to bus, train, or airplane. There might also be safety gains if some travel shifted from train to airplane, or from bus to airplane.

## THE COSTS OF ACCIDENTS

Most estimates of losses caused by transportation accidents are for road accidents.

In this section, we use Transport Canada's calculations of the property damage, lost work and health care costs associated with all road accidents and casualties. They are as follows:

*Property damage costs:* Data come from the claims records of insurance companies, and include allowances for unclaimed damage.

*Lost work costs:* Data come from durations of disability and average expectations of lifetime income, with allowance made for unpaid work performed in or outside of the home.

*Health care costs:* Estimates of these costs are derived primarily from records of payment by provincially owned motor-vehicle insurance administrations in British Columbia and Quebec.

Table 8-10 illustrates the estimated minimum loss per victim for death or injury. The losses arise mainly from lost work (including unpaid work at equivalent market values).

Table 8-10

ESTIMATED MINIMUM AVERAGE LOSSES PER VICTIM (ROAD), 1990

| Severity of injury | Loss per victim ($) |
|---|---|
| Fatal | 330,000 |
| Non-fatal | 10,000 |

**Sources: J.J. Lawson, "The Costs of Road Accidents and Their Application in Economic Evaluation of Safety Programs," Transportation Forum of the Roads and Transportation Association of Canada, V.2 (1980), pp. 53-63; J.J. Lawson, *The Valuation of Transport Safety* (Ottawa: Transport Canada, May 1989) Report TP 10569.**

Table 8-11 provides data on the components of costs, averaged per accident. Because accidents on average have more than one victim, the average costs per accident are higher than those per victim. There are about 115 fatalities for every 100 fatal accidents, and nearly 150 injured victims for every 100 injury accidents.

Table 8-11

ESTIMATED MINIMUM AVERAGE LOSSES PER ACCIDENT BY TYPE OF LOSS (ROAD), 1990

| Class of accident | Number of accidents | Health care ($) | Work loss ($) | Property damage ($) | Total ($) |
|---|---|---|---|---|---|
| Fatal | 3,440 | (few) | 400,000[a] | 10,000 | 410,000[a] |
| Injury | 178,854 | 2,000–3,000 | 12,000 | 10,000 | 25,000 |
| No injury | 650,000 | nil | nil | 5,000 | 5,000 |

**Sources: J.J. Lawson, "The Costs of Road Accidents and Their Application in Economic Evaluation of Safety Programs," Transportation Forum of the Roads and Transportation Association of Canada, V.2 (1980), pp. 53-63; J.J. Lawson, *The Valuation of Transport Safety* (Ottawa: Transport Canada, May 1989) Report TP 10569.**

**a. "Work loss" and therefore "totals" are uncertain.**

Table 8-12 estimates the minimum total losses for all road accidents in 1990, indicating that health care accounted for $500 million, work losses for $3.5 billion, and property damage for $5 billion.

*Table 8-12*
*ESTIMATED MINIMUM TOTAL LOSSES IN ALL ACCIDENTS BY TYPE OF LOSS (ROAD), 1990*

| Class of accident | Number of accidents | Health care ($ billions) | Work loss ($ billions) | Property damage ($ billions) | Total ($ billions) |
|---|---|---|---|---|---|
| Fatal | 3,440 | (few) | 1.4 | (few) | 1.4 |
| Injury | 178,854 | 0.5 | 2.1 | 1.8 | 4.4 |
| No injury | 650,000 | nil | nil | 3.2 | 3.2 |

**Sources: J.J. Lawson, "The Costs of Road Accidents and Their Application in Economic Evaluation of Safety Programs," Transportation Forum of the Roads and Transportation Association of Canada, V.2 (1980), pp. 53-63; J.J. Lawson, *The Valuation of Transport Safety* (Ottawa: Transport Canada, May 1989) Report TP 10569.**

The value of improved safety can be determined by estimating what people are willing to pay to reduce or avoid the risk of death. To do this, calculations are made using the following sources:

- additional wages received by workers in risky jobs;
- amounts paid by consumers for safety devices; and
- amounts individuals say they would pay to reduce a risk.

Some researchers have suggested that the value of life is in the $1 million to $3 million range. The debate on the value of life remains unresolved. The result is that governments around the world plan safety investments using different values.[13]

Transport Canada currently uses $1.5 million as a value per death avoided. If this amount reflects the social costs of the grief and suffering caused by an accident, as well as the costs of physical damage, lost work and health care, it would raise the total estimated annual accident cost shown in Table 8-12 from $9 billion to $14 billion.

## WHO PAYS FOR ACCIDENT COSTS?

Transportation vehicle users, owners and carriers today pay for 95 percent of the costs that result from property damage and work loss caused by road accidents. They pay through:

- mandatory third-party liability insurance to cover the losses of others in accidents;[14]
- personal collision insurance, which is optional;
- payment of deductible amounts in their insurance policies; and
- payment for uninsured damages.

Travellers pay the cost of accidents if their insurance compensates all losses fully and if the annual premium accurately represents the expected loss per year. The insurance company charges an annual premium based on the expected loss that year. In this manner, travellers facing similar risks share the costs occurring in any one year.

Do travellers pay for all the accident costs they incur? Not entirely, for three reasons:

- Insurance companies do vary the premium rates with different accident experiences but not by enough to avoid all cross subsidization. They spread risks too broadly among travellers with different accident experiences. While the *Canadian Charter of Rights and Freedoms* and some provincial legislation deter insurance companies from varying their rates according to sex and age, there remains scope for greater differentiation of insurance rates according to such factors as previous accident claims and traffic violations, area of residence, model of vehicle and annual distance travelled.
- Compensation to victims is not complete. Insurance pays only for losses deemed to have occurred, and the method for determining such losses differs from province to province. For example, the motor-vehicle insurance agency in Quebec provides generous

compensation for income losses to victims who are not employed. In Ontario, the no-fault system has low limits on many classes of compensation. Other provincial or territorial insurance systems also have caps on levels of compensation.

- Some accident costs are paid by others and not by those responsible. This is particularly true of health care costs, which are paid primarily by taxpayers. In 1990, the total health care cost from accidents was about $500 million (Table 8-12). Of this total, about $300 million was paid by provincial health-insurance plans, and only $200 million was recovered from motor-vehicle insurance companies.

The $300 million not recovered from transportation users is small in relation to total accident losses of $9 billion, and represents only 5 percent of total accident damage. Charging this amount to users would add 0.25¢ per vehicle-kilometre, or about $40 per vehicle per year to insurance premiums.

## WHO PAYS FOR THE COST OF ACCIDENT PREVENTION?

### INFRASTRUCTURE DESIGN AND SERVICES

When transportation providers design infrastructure to accommodate traffic capacity, they also build in a substantial amount of safety. The design of runways includes lengths and widths that are safe for landings and take-offs, and the design of roads has alignments, shoulders, and medians to provide safe driving conditions. Transportation infrastructure also includes navigation equipment, road barriers, markings and traffic control devices — all designed for both capacity and safety. Some services, such as emergency response systems, are strictly safety-oriented.

In general, the infrastructure provider bears the initial costs of design and safety features. Who ultimately pays depends on the extent to which the infrastructure provider tries to recover costs from travellers.

In general, taxpayers pay for the unrecovered costs of government-provided infrastructure through federal, provincial, territorial and municipal taxes.

### REGULATION OF OPERATORS AND PERFORMANCE

Government regulation of vehicle operators and vehicle performance is based on concerns that the marketplace alone cannot protect society's safety interests. For example, there are regulations to:

- protect innocent bystanders from reckless operators;
- protect passengers on public transportation from risks over which they have no control;
- protect vehicle purchasers who are unable to ascertain the safety performance of vehicles and equipment;
- overcome manufacturers' resistance to the expense of incorporating safety innovations in their equipment; and
- ensure that individuals protect themselves. For example, they require car drivers and passengers to use seat belts, motorcyclists to wear helmets, and children to use seats with child restraints.

In general, travellers today do not pay directly for the costs that governments incur in developing, monitoring and enforcing regulations. These costs include administering registration systems, testing vehicles and craft, and, most significantly, enforcing traffic regulations. In 1987, the most recent year for which we have data, the cost of police enforcement in Canada for safety regulations was approximately $450 million.

## RECOMMENDATIONS

As set out in Chapter 4, safety is an objective of the passenger transportation system. Therefore all safety costs should be incorporated into the price paid by travellers in each mode.

The health care system in Canada is intended to provide universal coverage. User-pay is consistent with this principle. We believe that charges can be levied on specific activities that contribute to health care costs. This will reduce the funds that need to be provided to the health care system from general tax revenues and health care taxes and premiums. The Canadian taxpayer also bears most of the government cost of developing, monitoring and enforcing regulations that promote transportation safety. We believe that travellers should also pay for these costs.

We therefore **recommend** that:

**8.1 Travellers pay for all safety and accident costs, including:**

**(a) health care costs related to passenger transportation currently borne by the health insurance system; and**

**(b) the cost of safety services provided by governments.**

Provincial and territorial authorities may already be setting their vehicle licence fees to include regulation costs, particularly for police enforcement. If they are doing so, these costs are not evident to the public. We believe that it is feasible for the provinces to account for those costs more specifically and to include them in the prices they charge to transportation users.

Until recently, Transport Canada used widely differing values for the different modes in assessing safety improvements and evaluating spending proposals. For example, the values of life and of various injuries used in aviation safety decisions were several times higher than those used in road safety decisions. Whether this difference in values led to any large distortion in government spending by mode is not clear. We think it likely, however, that government spending priorities would have been different if, for example, the aviation values had been used to assess investments, regulations and other policies across all modes.

Furthermore, it appears that the provinces also made spending decisions on improvements for road safety based on Transport Canada's road values. Had aviation values been used instead, highway safety investments might have increased substantially.

This possible federal bias towards aviation safety and against road safety may be eliminated now that the Department has proposed a uniform value for all modes.

To ensure this, we **recommend** that:

---

**8.2 All responsible agencies use comparable values for injury and loss of life when evaluating spending proposals for safety improvements in different modes.**

# ENDNOTES

1. Other accidents in private vehicles are excluded from these figures (for example, those killed or injured in private flying, private boating and non-passenger shipping).

2. For more detailed information on the modes of travel, general developments in safety, and comparisons of safety risks by mode, see Volume 2.

3. The following statistics describe the safety of Canadian-registered carriers, including their foreign as well as domestic operations, and do not represent operations in Canada of foreign carriers. Note that carriers can also be designated as level 1 or 2 on the basis of tonnes of freight carried.

4. This category includes the two major airlines, Air Canada and Canadian Airlines International Ltd., and two feeder airlines, Air BC and Time Air.

5. This category currently includes 24 major (feeder and charter) air carriers, including for example, Nationair, Canada 3000 Ltd., Air Nova and Air Ontario.

6. This category currently includes some 844 smaller operators, including such companies as Air Creebec, Labrador Airways and Athabaska Airways. Only a minority of these companies appear to provide scheduled passenger service. Few data are available on the almost 600 operators in levels 5 and 6.

7. These statistics include accidents to Canadian carriers whether occurring in Canada or abroad.

8. A death rate of 0.05 per billion passenger-kilometres converts to 1 death per (1 billion ÷ 0.05 =) 20 billion passenger-kilometres.

9. In the decade 1981 to 1990, 9.6 million hours of private flying time were logged. If the aircraft averaged 250 to 300 kilometres per hour and 2 to 3 passengers, the 556 private-flying deaths during the decade would indicate a fatality rate of 60 to 120 deaths per billion passenger-kilometres.

10. Some U.S. observers had been concerned that deregulation would increase accident risks because traffic from the safer major carriers would switch to less-safe commuter carriers. This fear has not been substantiated. While switching has occurred, most traffic shifted to larger commuter carriers, whose accident rates were below the average for commuter carriers.

    Also, the higher fatality rates for commuter carriers reflect, in general, their shorter trip lengths and greater number of take-offs and landings, which is when airplanes are at most risk of crashing. Following deregulation, commuter airlines became part of the hub-and-spoke pattern of airline routing, whereby travellers fly to a central airport (the hub) and change planes to travel to other destinations via the spokes. The somewhat unexpected result was that the overall number of stops on a typical passenger's flight was reduced, thereby improving the commuter carriers' safety.

    Overall, researchers conclude that, while the increase in commuter traffic possibly worsened average risks per passenger-kilometre compared with what might have been achieved without deregulation, air safety continued to improve.

11. See L.F. Bylow and I. Savage, "The Effect of Airline Deregulation on Automobile Fatalities," *Accident Analysis and Prevention* 23 (5), October 1991, pp. 443-52.

12. Verbal communication from those responsible for Transport Canada's motor vehicle accident investigation teams.

13. Until recently, different values were even used within Transport Canada. Aviation investment analysts placed a value on death avoided that was several times higher than the value used in evaluating motor vehicle regulations and highway investments. Uniformity was established when the Department adopted a standard value of $1.5 million (in 1991 dollars). That figure is essentially a median value among those previously used, and Transport Canada makes no claim to have resolved the problems of measuring the value of life.

14. There are provincial variations regarding insurance. Some provinces have no-fault insurance programs: Ontario for all third-party damage, Quebec for all injury, and others with elements of no-fault in agreed payment schedules for specified damages.

    In addition, British Columbia, Saskatchewan and Manitoba have provincial insurance companies for all motor-vehicle insurance, and Quebec has a provincial scheme for injury damage, leaving property damage to private-sector insurance companies. All provinces have no-fault hospital-medical insurance schemes that provide health care for victims regardless of who was responsible for the accident.

# CHAPTER 9

# EASING THE WAY: ACCESS TO TRANSPORTATION FOR PEOPLE WITH DISABILITIES

## INTRODUCTION

Our public hearings and review of submissions made us keenly aware that many Canadians with disabilities must struggle to gain access to transportation services. For example, some feel cut off from public transportation because it is difficult to find appropriate seating or to get on and off buses, trains and airplanes. Others have problems moving around terminals, hearing announcements or reading signs. For many, travel becomes so arduous that they are unable to use public transportation at all.

Canadians with disabilities believe that equal access to transportation will allow them to lead more independent and productive lives. When these Canadians spoke with us about their difficulties with the transportation system, many said that they are unable to travel to educational, vocational, cultural and commercial facilities in and beyond their communities. They asked for the same access, comfort and dignity that other Canadians take for granted. They also made numerous suggestions on how access to the passenger transportation system could be improved.

## THE CURRENT SITUATION: FRUSTRATION AND PROGRESS

### THE PEOPLE MOST AFFECTED

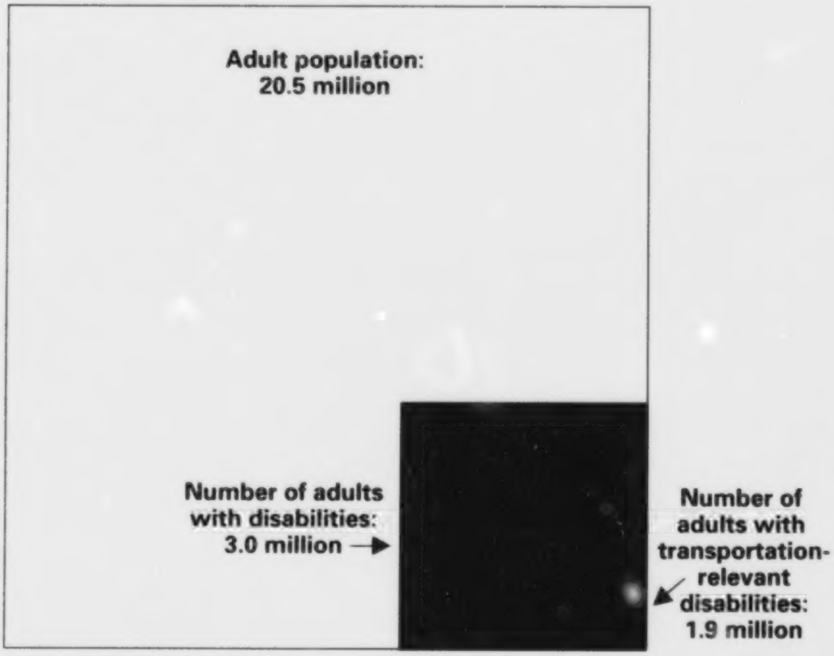
Chart 9-1 shows the relationship between the adult Canadian population, the component composed of people with disabilities, and the number of Canadians in this smaller population who have transportation-relevant disabilities.[1] This latter group accounted for nearly 10 percent of the adult population, and 63 percent of adults with disabilities (or about 1.9 million people) in 1990.[2]

The amount of change required to improve accessibility for people with disabilities differs depending on the nature of the disability. In some cases, specialized training of transportation personnel is sufficient; in others, additional or modified equipment is necessary.

Table 9-1 provides an estimate of the number of Canadians with transportation-relevant disabilities, by type of disability. In 1990,

*Chart 9-1*

*NUMBER OF ADULTS WITH DISABILITIES AND WITH TRANSPORTATION-RELEVANT DISABILITIES, 1990*



**Source:** Hickling Corporation, ***Transportation for People with Disabilities: A Policy Review and Analysis***, **a report prepared for the Royal Commission on National Passenger Transportation, RR-01, March 1991.**

adult Canadians who have to use wheelchairs or walkers when they travel numbered an estimated 132,660, or 7.1 percent of those with transportation-relevant disabilities.

*Table 9-1*

**NUMBER OF PERSONS WITH TRANSPORTATION-RELEVANT DISABILITIES, BY TYPE OF DISABILITY, 1990**

| | Number | Percent[a] |
|---|---|---|
| All Canadians aged 15 and over with transportation-relevant disabilities | 1,879,615 | 100.0 |
| Mental disability | 714,398 | 38.0 |
| Hearing impairment | 648,780 | 34.5 |
| Sight impairment | 417,990 | 22.2 |
| Speech impairment | 159,843 | 8.5 |
| Wheelchair or walker use | 132,660 | 7.1 |
| Blindness | 42,176 | 2.2 |
| Disability unspecified | 37,052 | 2.0 |

Sources: Hickling Corporation, using data from Statistics Canada's Health and Activity Limitation Survey, 1987, with projections to 1990; *Transportation for People with Disabilities: A Policy Review and Analysis*, a report prepared for the Royal Commission on National Passenger Transportation, RR-01, March 1991, p. 5.

a. Figures will add to more than 100 percent because some people have multiple disabilities. Figures include people living in institutions but exclude those confined to the home (an estimated 37,600).

Today, Canadians over 65 years old make up only 11 percent of the population but account for nearly 37 percent of those with disabilities.[3] By the early part of the next century, that 11 percent will rise to 18 percent — about 6 million people. It is likely that there will be a proportionate increase in the number of Canadians with disabilities.[4] This poses challenges for governments today, and for transportation providers who must plan for the future use of transportation infrastructure and services.

## EXPECTATIONS FOR IMPROVEMENT IN ACCESS

There have been several pieces of legislation in Canada and the United States in recent years that raised expectations of rapid improvements in access to transportation for people with disabilities. In Canada, Parliament passed the *National Transportation Act, 1987,* which states that no carrier or mode of transportation under federal jurisdiction "so far as practicable" should allow "an undue obstacle to the mobility of persons, including those persons who are disabled."[5] The Act also gives the National Transportation Agency responsibility for "eliminating undue obstacles in the transportation network governed by this Act to the mobility of disabled persons."[6] In the United States, Congress passed the *Americans with Disabilities Act of 1990*. With respect to passenger transportation, this Act requires carriers to meet, over specified time periods, standards of accessibility for people with disabilities.[7]

In Canada, people with disabilities expected that the Canadian legislation plus the influence of the American legislation would bring about quick and considerable improvements in their access to passenger transportation. This did not happen. It has taken five years for the federal government to publish, for comment, proposed regulations aimed at improving access to transportation services for people with disabilities. These proposed regulations apply only to the domestic carriage of people with disabilities in aircraft with 30 or more passenger seats and to programs for carrier personnel training.[8]

## WHAT PROGRESS HAS BEEN MADE?

People with disabilities and those who support their efforts to improve accessibility are putting pressure on governments and industry in different countries to recognize that they are entitled to equality with those who do not have a disability. In the United States, for example, Vietnam veterans' groups were active in the movement that led Congress to enact the *Americans with Disabilities Act of 1990.*

In Canada, several pieces of legislation address issues of importance to those with disabilities. Two that provide a measure of protection are the *Canadian Charter of Rights and Freedoms* and the *Canadian Human Rights Act.*[9] The provisions relevant to transportation, however, require the traveller with a disability to seek access, rather than placing the onus on service providers to ensure it. Furthermore, under this legislation, knowledge of lack of access is not sufficient grounds to seek redress — a person with a disability must first have been refused access. In contrast, the *National Transportation Act, 1987* provides authority to initiate action to require transportation carriers to eliminate undue obstacles.

Government and industry are improving access, but progress is slow. Although legislation and regulation provide incentives, we have found that improvements are often begun hesitantly and implemented slowly. We note, however, the following efforts on behalf of travellers with disabilities.

### The National Transportation Agency[10]

In line with the responsibilities given to it in the *National Transportation Act, 1987*, the Agency has initiated several activities:

- The Agency issued several individual orders to improve access after complaints were lodged.[11]
- The Agency reported on May 27, 1991 on an inquiry into the policies of Canadian air carriers regarding people with disabilities.[12] The inquiry found that one airline had a policy of not accepting travellers with certain disabilities on specific aircraft and asked the airline to comment on the inquiry's finding that this policy may constitute an "undue obstacle to the mobility of disabled persons."

  In general, the inquiry found that the policies of large carriers do not appear to pose major problems to passengers with disabilities. It noted, however, that these policies are discretionary and subject to change by the companies without notice, and could lead to obstacles to the mobility of travellers. The inquiry suggested that future obstacles could be avoided if an overall policy with uniform terms and conditions for all air companies were put in place.

- The Agency announced an inquiry on March 19, 1991 into the accessibility of ferry services under federal jurisdiction. This inquiry is expected to recommend regulations that remove barriers to mobility that arise from the construction or design of ferry equipment and terminals, operating policies, training of ferry staff and communication of information to people with disabilities. The inquiry issued its interim report on January 17, 1992, and requested further comments, suggestions or new information from ferry operators and other interested parties.[13]
- Another inquiry is examining the accessibility of Canada's interprovincial bus system. This inquiry, which commenced in the spring of 1992 and includes public hearings in centres across the country, will report to the Minister of Transport in the spring of 1993.[14]
- On March 21, 1992, the Agency published its proposed regulations in two areas.[15] The first area covers the services to be provided to people with disabilities travelling in airplanes with 30 or more passenger seats. The second area discusses the training to be provided to personnel employed by all federally regulated carriers and terminal operators to enable staff to assist travellers with disabilities in the most appropriate ways.

## Recent Legislative Initiatives

On May 5, 1992, the Secretary of State tabled Bill C-78, which was aimed at improving accessibility to various services for people with disabilities by amending six Acts. The Acts are the *Canada Elections Act*, the *Access to Information Act*, the *Privacy Act*, the *Criminal Code*, the *Citizenship Act* and the *National Transportation Act, 1987*.

The bill was passed on June 18, 1992. The preamble to the *National Transportation Act, 1987* (NTA, 1987) now includes access for people with disabilities as part of the overall objectives for Canada's transportation system.[16]

In the news release announcing the tabling of the Bill, the Secretary of State noted that the NTA, 1987 amendment was in addition to the recent pre-publication of two sets of regulations to improve access to the federally regulated transportation system. He announced that "Additional CDRC [Canadian Disability Rights Council] proposals for improving transportation accessibility will be considered as part of an independent review of the *National Transportation Act, 1987* to be completed next year."[17]

The Secretary of State also indicated that Treasury Board will strengthen and promote its policy regarding the way in which the federal government communicates with persons with disabilities. This should result in more information concerning government programs and services — including transportation services — becoming available in alternative formats such as braille, large print, computer-readable diskettes and TDDs (Telecommunications Devices for the Deaf).

### Federal Government Programs

The federal government has provided funding for demonstration projects, workshops, communications projects and research to improve accessibility for people with disabilities. In 1990, funding for these projects totalled $1.5 million. One major demonstration project for intercity busing was funded by Transport Canada and implemented through Canada Coach Lines between the Ontario cities of Kitchener, Cambridge, Hamilton, St. Catharines and Niagara Falls. Use of this service, however, was low.[18]

The National Strategy for the Integration of Persons with Disabilities, announced in the fall of 1991, provides $24.6 million over a five-year period to help carriers improve access to their vehicles, and to develop training programs that encourage employees of federally regulated carriers to develop more positive attitudes and practices towards people with disabilities.[19]

### Municipal, Provincial and Territorial Government Programs

Although municipal governments are not generally concerned with intercity transportation, we recognize that they play an important role in ensuring that people with disabilities are able to reach air, rail, bus and ferry terminals.

Accessible taxis and para-transit are generally the responsibility of municipal governments but are, in many instances, funded jointly with provincial governments. Although provincial governments have acted in various ways to improve access, most of their funding goes for para-transit services that provide specialized transportation, such as vans with wheelchair lifts, in urban areas.

Other provincial and territorial activities have included financial support for vehicle retrofits of hand controls and lifts, special parking permits, transportation assistance for people with disabilities in rural areas, and demonstrations of wheelchair-accessible taxis.

### Industry Initiatives

Canada's major scheduled airlines, their affiliates and other independent airlines have voluntarily put in place services to assist travellers with disabilities. These services include reduced fares for attendants on flights within North America; in-flight wheelchairs and oxygen; wheelchair-accessible washrooms on many aircraft; and a toll-free telephone number in Canada for those with a Telecommunications Device for the Deaf.

For people with disabilities, access to major ferry and rail services is generally easier than to intercity bus services. Many ferry, rail and major bus companies do not charge for an attendant accompanying a person with a disability.

## RECOMMENDATIONS

While governments and industry have taken steps to improve access to intercity passenger transportation for people with disabilities, still more must be done. We make the following recommendations so that the pace of improvement will increase.

## RIGHTS TO ACCESS

We firmly believe that the transportation independence of all Canadians is important. When people with disabilities have access to jobs and educational facilities, they have a better chance of becoming productive and participating citizens who add to the vitality and diversity of Canadian society.

Therefore, we **recommend** that:

**9.1 Governments establish a goal that all travellers in Canada have access to public transportation in a safe, reasonably comfortable and dignified fashion, irrespective of physical or mental ability.**

**9.2 The National Transportation Agency establish minimum national standards of passenger accessibility. As with other related initiatives, these should be developed in consultation with groups representing people with disabilities, carriers and operators of transportation infrastructure.**

## MAKING EQUIPMENT AND INFRASTRUCTURE ACCESSIBLE

We recognize that there are many obstacles to providing accessible transportation for people with disabilities. Currently, people with transportation-relevant disabilities form only 10 percent of Canada's adult population. Even though that percentage is expected to rise, the proportion of Canadians with disabilities who wish to travel will remain low compared with the rest of the population. As a result, their demand for specialized transportation services may never be enough to lead to the provision of these services on a purely market-driven basis. In addition, individual point-to-point services and modification of equipment and services to improve accessibility — especially for the few travellers with ambulatory disabilities — are expensive.

The range of physical abilities that should be considered when providing access to passenger transportation services has been expanding. We wish that all obstacles to accessible transportation could be removed immediately, but recognize that imposing costly, immediate requirements upon Canadian carriers could undermine their viability.

At present, it may be more practical for some modes to operate accessible services parallel to existing public transportation (for example, the para-transit bus services in some municipalities). We believe, however, that people with disabilities should be as fully integrated into Canadian life as possible, and that one system to handle all travellers should be the long-term goal.

We believe that improved accessibility can often be accomplished at modest additional cost, by changing operating rules, sensitizing carrier staff, improving the design of new equipment and infrastructure, and modifying existing equipment and infrastructure. Other changes, unfortunately, are more costly.

Therefore, we **recommend** that:

---

**9.3 Carriers and providers of infrastructure begin now to ensure that their specifications for new equipment and infrastructure will provide people with disabilities with continuing improvements in accessibility to their services. They should also implement, where practicable, retrofitting programs for their equipment and infrastructure.**

---

Implementing this recommendation will result in substantial improvements in access for most individuals who currently find intercity travel either difficult or impossible. In some cases, further efforts are needed to ensure that the technologies and operating procedures devised to assist travellers with disabilities are appropriate, yet cost-effective.

We want to ensure that regulations dealing with accessibility for people with disabilities lead to continuing improvements.

Therefore, we **recommend** that:

---

**9.4 The *National Transportation Act, 1987* be amended to require that the National Transportation Agency take more active responsibility for ensuring that transportation services become more accessible to those with disabilities.**

---

## CARRIER COSTS

Improving accessibility for travellers with disabilities will undeniably add costs to carrier operations, which will be passed on to all travellers. We considered how our recommendations for the treatment of travellers with disabilities would affect carriers' operations in a competitive market, and wanted to ensure that the modes do not face unforeseen costs in the short term.

Therefore, we **recommend** that:

---

**9.5 The National Transportation Agency, in taking more active responsibility for ensuring that transportation services become more accessible to those with disabilities, give carriers and operators of transportation related infrastructure:**

**(a) the freedom to decide how best to meet performance standards, rather than giving them detailed directions on how accessibility is to be achieved; together with**

**(b) a reasonable period of time to improve accessibility to new equipment and to infrastructure.**

---

## ATTENDANTS AND IDENTIFICATION CARDS

We are aware of the stress and frustration that people with disabilities often experience because of administrative obstacles when trying to obtain or use specialized services. Some carriers, for example, have required clients with disabilities to obtain documentation regarding their ability to travel before accepting them as passengers, and sometimes required that this documentation be shown before each trip. Other carriers have insisted that passengers with disabilities must travel with an attendant, even though the passenger did not feel that an attendant was needed. On the other hand, for some people with disabilities, safe and comfortable travel can only be achieved with the help of an attendant.[20]

Whatever the special needs or services required by people with disabilities, we feel that these should be determined privately, prior to the trip. Wherever possible, we would like to eliminate what are sometimes embarrassing discussions at check-in counters and other points of departure about special arrangements and services.

Government, industry and groups representing people with disabilities should develop a mechanism that allows travellers with permanent or long-term disabilities to eliminate the need for discussion and questioning on each travel occasion.

We recognize that the condition of an individual with a permanent disability is not necessarily stable and, in some cases, the requirement for an attendant could change. The mechanism created should allow for periodic reviews of some decisions. One way of handling decisions relating to the needs of travellers with disabilities could be through the use of coded identification cards.

Therefore, we **recommend** that:

---

**9.6 Through consultation among groups representing people with disabilities, carrier associations and the National Transportation Agency, a mechanism such as a coded identification card system be devised that would indicate quickly to carrier personnel the kinds of services needed by each traveller with a disability, including whether or not the traveller requires an attendant for safety or other reasons.**

---

Coded identification cards could:

- identify those travellers requiring assistance with such activities as boarding, eating and using the washroom;
- indicate whether a traveller requires an attendant on some or all types of trips;
- indicate whether the need for an attendant applies to one or more modes of transportation;
- identify those travellers who do not require an attendant, so that such passengers are not refused access because they are unaccompanied; and
- be valid for use on all carriers.

We recognize that there may be situations where a carrier requires that, for safety reasons, a person with a disability be accompanied by an attendant.

Therefore, we **recommend** that:

---

**9.7 The National Transportation Agency be appointed as the referee to mediate quickly disputes over the need for an attendant. In situations that are difficult to decide, the safety of all travellers, including the traveller with the disability, should be given primary consideration.**

---

**9.8 When the National Transportation Agency or the carrier concludes that, for safety reasons, an attendant is needed during a trip to assist an individual with a disability, the attendant's fare be borne by the carrier. Otherwise, the traveller should bear the cost. To ensure consistency, carriers should coordinate their policies in this area.**

---

## TRAINING OF TRANSPORTATION PERSONNEL[21]

During our hearings and in the written submissions we received from groups representing people with disabilities, we were told many times how important the attitudes of transportation personnel were in their dealings with travellers with disabilities. We learned that negative and uncooperative attitudes often result from lack of knowledge, experience or training on the part of transportation staff.

Therefore, we **recommend** that:

---

**9.9 Carriers ensure that personnel who are in a position to assist travellers with disabilities be trained to deal with such passengers with sensitivity and understanding.**

---

## COMFORT

Travellers with disabilities need both access to transportation infrastructure and services and the ability to travel with comfort and dignity. We recognize that levels of comfort for travellers with disabilities may not be equal to those for travellers without disabilities, but we believe that carriers must show reasonable efforts to improve these levels.

## INTERCITY BUSES

We are concerned that intercity buses, which are provincially regulated, are not always as accessible as airplanes, trains and ferries, which are federally regulated. Differences exist among the provinces and territories in their efforts to improve transportation access. We want to see improved accessibility to this important mode of passenger transportation — and a reduction of the disparities across the country.

Therefore, we **recommend** that:

---

**9.10 Provincial and territorial governments implement more-uniform and adequate minimum accessibility standards for intercity buses for travellers with disabilities, or, if that does not occur, the federal government take back its delegated responsibility for nationally applied accessibility standards in order to ensure more uniformity.**

---

## COORDINATION OF EFFORTS

Various committees and groups provide a forum for the discussion of accessible transportation. The federal Minister's Advisory Committee on Accessible Transportation is composed of groups representing individuals with physical and mental disabilities as well as representatives from the transportation industry such as air and bus carrier associations, VIA Rail and Marine Atlantic Inc. The National Transportation Agency also has an equipment accessibility advisory committee, whose members include representatives of people with disabilities, and air, rail, bus and ferry carriers.

Over the next few years, a delicate balance must be struck. While it is in everyone's interest in the long term to improve the integration of people with disabilities into Canadian society, in the short term some changes can be implemented more quickly than others. In recognition of this, we believe that advisory committees, with members representing a broad spectrum of interests, will play a critical role in finding this balance. For instance, we recognize that improving accessibility to small vehicles may be more difficult or proportionately more costly than doing so with large ones. And yet we also do not want to undermine the development of a highly flexible system to meet the transportation needs of all Canadians (including those living in sparsely populated areas) by creating a bias against small vehicles such as minivans and small aircraft.

In addition, members of these committees can bring to the government's attention examples of where government policies and regulations in non-transportation areas impede improved accessibility to transportation. We believe that these advisory committees provide an important communications link in the development of accessible transportation for those with disabilities.

Therefore, we **recommend** that:

**9.11 Canadians with disabilities, governments, carriers and manufacturers actively use advisory and coordinating groups to ensure that new services, equipment and infrastructure adequately serve those for whom they are intended, and to ensure that Recommendations 9.1 to 9.10 are implemented.**

Access to passenger transportation will allow Canadians with disabilities to lead more independent and productive lives. We believe our recommendations will help ensure that access. When people with disabilities have more access to educational and vocational facilities, they will become more independent and productive. The Canadian economy will benefit and this will go a long way to offset society's expenditures on improvements. In other words, an investment in accessibility has good potential for return.

# ENDNOTES

1. The adult population includes people 15 years of age and over. People with transportation-relevant disabilities are those who, because of a physical or mental condition, cannot use one or more passenger transportation services, or experience more than average difficulty doing so. See Hickling Corporation, *Transportation for People with Disabilities: A Policy Review and Analysis,* a report prepared for the Royal Commission on National Passenger Transportation, RR-01, March 1991, p. 3.

2. These data are drawn from a survey carried out by Statistics Canada in 1986 and 1987 and reported in *The Health and Activity Limitation Survey. Highlights: Disabled Persons in Canada,* Catalogue No. 82-602, March 1990. The survey was repeated in 1991 and the data are being released in phases. Several questions were added to the transportation section of the questionnaire. These data are scheduled for release in the summer of 1993.

3. These data are also from Statistics Canada's *Health and Activity Limitation Survey* of 1986 and 1987. The 1991 survey data relating to the discussion of the size of the population with disabilities will be available in the fall of 1992.

4. As mentioned in our Interim Report, disability increases dramatically with age in the "over 65" category — that is, from 36.7 percent for those aged 65 to 74 years, to 53.6 percent for those aged 75 to 84, and to 82.1 percent for those over 85 years of age. See *Getting There: The Interim Report of the Royal Commission on National Passenger Transportation* (Ottawa: Supply and Services Canada, April 1991), p. 114.

5. Section 3.(1) of the *National Transportation Act, 1987.* This is reprinted in Volume 2 of this report.

6. This responsibility is given in sections 63.1 to 63.3 of the *National Transportation Act, 1987.* The sections are reprinted in Volume 2 of this report.

7. Further details of the U.S. accessibility standards for persons with disabilities are noted in Volume 2 of this report.

8. Further details regarding these regulations may be found in Volume 2 of this report.

9. The relevant sections of the *Canadian Charter of Rights and Freedoms* and the *Canadian Human Rights Act* are reprinted in Volume 2 of this report.

10. Further details of the Agency's activities are included in Volume 2 of this report.

11. These agency orders are noted in Volume 2 of this report.

12. National Transportation Agency of Canada, *Communiqué,* May 27, 1991.

13. Kenneth A. Mozersky, Anne M. Hampel and Paul Lacoste, *Interim Report of the Inquiry into Level of Accessibility of Ferry Services* (Ottawa: National Transportation Agency of Canada, January 17, 1992).

14. National Passenger Transportation Agency of Canada, *Communiqué,* March 11, 1992.

15. *Canada Gazette,* Part I, March 21, 1992, pp. 706-24.

16. The preamble now reads as follows (addition in italics):

    3.(1). It is hereby declared that a safe, economic, efficient and adequate network of viable and effective transportation services *accessible to persons with disabilities* and making the best use of all available modes of transportation at the lowest total cost is essential to serve the transportation needs of shippers and travellers, *including persons with disabilities*, and to maintain the economic well-being and growth of Canada and its regions and that those objectives are most likely to be achieved when all carriers are able to compete, both within and among the various modes of transportation, under conditions ensuring that, having due regard to national policy and to legal and constitutional requirements. . . .

17. Secretary of State of Canada, news release 92-010, May 5, 1992.

18. The purpose of this demonstration project was to assess the demand for an accessible intercity bus service and the economics of such a service. During the first 21 months of the project, 242 trips were made by people with disabilities (an average of 12 trips per month). Of these trips, 97 percent were made by passengers in wheelchairs. Forty-one people with disabilities used the service but two individuals made 47 percent of all the trips. The number of trips taken by people with disabilities equalled approximately 0.04 percent of the total trips taken. Further details are provided in Volume 2 of this report.

19. Further details are provided in Volume 2 of this report.

20. The proposed National Transportation Agency regulations published on March 21, 1992, indicate that "an air carrier shall accept the determination made by or on behalf of a person that the person does not require any extraordinary service during a flight." In this case, however, "extraordinary service" means "any service related to a disability that is not required by [the regulations] to be provided by an air carrier or any service that is not normally provided by an air carrier."

21. On March 21, 1992, the National Transportation Agency published its proposed regulations on the training to be provided to personnel employed by carriers and transportation related premises and facilities to enable them to assist travellers with disabilities in more appropriate ways. These have not yet been put into effect.

# CHAPTER 10

# APPLYING THE PRINCIPLES TO CARRIERS: AN OVERVIEW

## INTRODUCTION

In previous chapters, we set out our principles and applied them to the providers of infrastructure and to governments, who are responsible for promoting environmental protection and transportation safety and for ensuring that the needs of people with disabilities are addressed. In this and the next four chapters, we apply our principles to the providers of passenger transportation services. In Chapters 11 to 14, we deal exclusively with public carriers — firms offering services to the public. We discuss the changes in federal and provincial/territorial policies that are necessary to achieve pressures for efficient performance. In addition, we set out transitional mechanisms for carriers requiring time to adjust to our principles. In this chapter, however, we also note the role of private carriers — individuals and firms that provide their own transportation using private cars and aircraft.

## PRIVATE CARRIERS

In Canada, private passenger carriers include the users of about 10 million cars, 3 million vans and light trucks, and 10,000 private aircraft.[1] In addition, passenger travel to points not served by road, mostly small islands and settlements along rivers and lakes, is provided by private boats.

Taxpayer expenditure for private boat passenger travel, as distinct from recreational boating, fishing and freight shipping, is not substantial. Operators usually know local waters well and require few navigational aids, and they pay fuel (mostly gasoline) tax. Taxpayer involvement with the private car and private plane is more important.

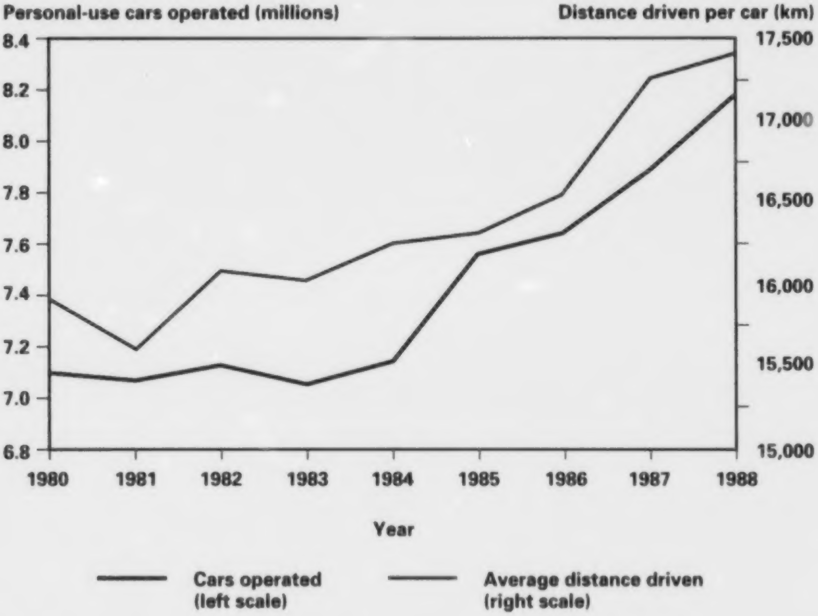
## TRAVEL BY PRIVATE CAR

Statistics show that the car is Canadians' preferred mode of intercity travel:

- in 1991, about 83 percent of all households owned one or more cars (including vans and light trucks), and 39 percent of all households owned two or more cars;
- in 1990, 68 percent of the population and 88 percent of the population 16 years of age and over, were licensed to drive;
- in 1990, household expenditures on cars for both urban and intercity purposes amounted to 84 percent of total personal expenditures on transportation, and about 11 percent of overall personal expenditures;
- in 1990, 91 percent of all domestic intercity round trips were by car;[2] and
- in 1990, around 80 percent of all domestic intercity kilometres travelled were by car.[3]

Chart 10-1 shows that both the number of cars and the use of these cars — as measured by estimates of average kilometres driven — increased between 1980 and 1988. (The data on which the chart is based are restricted to personal-use cars — not including personal-use vans and light trucks. The trends shown, however, are believed to be representative for "cars" as the term is used in this report.) Some transportation observers believe that public transit and electric vehicles will become increasingly attractive means of travel within cities. While this development could reduce the popularity of the car and its importance in intercity travel, current evidence indicates that the dominant position of car travel is increasing, rather than diminishing.

*Chart 10-1*
*Average Distance Driven, by Personal-Use Passenger Cars, 1980–1988*



**Sources:** 1980–Third Quarter 1983: Statistics Canada, *Fuel Consumption Survey*, Catalogue No. 53-226, December 1987; Fourth Quarter 1983: Statistics Canada, *Passenger Car Fuel Consumption Survey*, October 1984; 1984–1988: Statistics Canada, *Fuel Consumption Survey*, Catalogue No. 53-226, February 1990, summary tables in Parts 1–5.

**Note:** This chart shows data for personal-use cars, rather than for cars, vans and light trucks in all private uses. In general, the text refers to data on the latter basis.

Under our principles, each traveller should pay the full cost of his or her travel, and travellers, in total, should pay the full cost of the passenger transportation system, including those costs related to safety, accidents and protecting the environment.

Therefore, car users should pay for the costs they impose on roads, the health system and the environment. The proposed system of charges will require:

- adjusting licence fees and fuel charges so that road users pay for all road costs;

- introducing charges that pass on to car users the costs that the health care system and provincial/territorial systems of vehicle safety regulation and enforcement incur on their behalf; and
- increasing emission controls and charges in order to reduce vehicle pollution and to pass on to car users the costs of any remaining environmental damage they cause.

When car users pay the full costs of their travel, they will be more sensitive to the way their travel affects health care and the environment. Since cars form a major part of the passenger transportation system, changes in car travel and purchasing behaviour, based on an appreciation of the true costs of car use, will contribute substantially to the efficiency of the passenger transportation system.

## TRAVEL BY PRIVATE AIRPLANE

It is estimated there are 10,000 registered and active private aircraft in Canada. They fly an average of 80 hours a year. Apart from being limited to a small number of landing slots at the busy Vancouver and Toronto airports, private aircraft do use the public services designed for the aviation industry.

There are some 32,000 holders of private pilot licences in Canada. These licences are renewable without fee every one or two years, depending on the age of the pilot, and subject to medical examination.

Private aircraft, by virtue of provisions in the federal fee schedules, pay only a small portion of the costs of aviation services. With the exception of Vancouver and Toronto international airports, piston aircraft — and 98 percent of private aircraft are piston driven — pay no landing fees; instead, at federal airports they pay a per-litre fuel concession fee. The annual revenue from this 5¢-per-litre charge is about $2 million and is the only air infrastructure charge levied on private aircraft. This charge can easily be avoided by confining fuel purchasing to non-federal airports.

Private aircraft pay no terminal building fees because this fee schedule exempts aircraft with fewer than 10 seats. Private aircraft also do not pay the Air Transportation Tax, because the tax is applied to the selling price of a passenger's airline ticket. The Air Transportation Tax is used in substantial part to cover the costs of the local/tower aircraft control and enroute air navigation systems. About 95 percent of private aircraft use towered airports and more than 90 percent of private aircraft use different enroute navigation services from those used by the commercial airlines.

The level and structure of charges to private aircraft clearly require revision. Private aircraft operators, like all other users of the transportation system, should pay for what they get.

The changes in the charging systems for use of airports and of air navigation and traffic control systems, which we recommended in Chapter 5, will increase charges to private aircraft operators if they continue to use the air navigation and traffic control services currently provided.

## PUBLIC CARRIERS

In Chapters 5 to 9, we examined public and private carriers' use of transportation infrastructure, the responsiveness of their services to the needs of people with disabilities, and the environmental and accident costs of their transportation activities. In Chapters 11 to 14, we apply our principles to the operations of public carriers (airplane, train, bus and ferry) and examine major policy issues that arise regarding direct subsidies to carriers, economic deregulation and government ownership. The remainder of this chapter provides an overview of the issues to be discussed in Chapters 11 to 14. These chapters concentrate on issues of particular importance to the mode in question. We reiterate, however, that the principles for carriers (stated in Chapter 4) apply to all modes.

In this report, we are examining the conditions necessary to achieve a transportation system that is fair and efficient and meets appropriate standards of safety and environmental protection. The first condition is that all travellers, whether using public or private carriers, pay the true costs of their activities. The second is that public carriers face market pressures to respond to consumer preferences and to reduce costs, improve efficiency, and pass the resulting savings on to travellers.

Our aim of creating a truly competitive environment for intercity passenger transportation is consistent with the principle of the *National Transportation Act, 1987,* that "all carriers [be] able to compete both within and among the various modes of transportation."

In Chapter 4, we emphasized the importance of a competitive environment for public carriers and the need to:

- allow anyone who is "fit, willing and able" an opportunity to supply passenger carrier services;
- provide all carriers who are willing to pay their share of the costs with equal access to infrastructure; and
- permit carriers to withdraw their services, without undue delay, subject to adequate notice.

## "FIT, WILLING AND ABLE"

When we recommend that operators be "fit, willing and able" before entry to Canada's public passenger transportation industry, for the most part, we are not specific as to the appropriate screening criteria. In general we have in mind any operator who complies with safety regulations and has proof of adequate insurance coverage.

In the Canadian air passenger industry, except in the North, market entry regulation is restricted to fit, willing and able criteria. Under the *National Transportation Act, 1987,* in domestic service, an applicant must:

- meet Canadian ownership and control requirements;
- hold a Canadian aviation document in respect of the service to be provided — issued after the technical qualifications of the key personnel are established; and
- have prescribed liability insurance coverage or evidence of such insurability.

Here, we note the implications of the Commission of Inquiry into the Air Ontario Crash at Dryden, Ontario — that both fitness and ability should be monitored on an ongoing basis, and not be simply requirements that must be (temporarily) satisfied when the licence is first obtained.

Under the *Railway Act*, incorporation of a company that wishes to construct or operate a railway in federal jurisdiction using new track must prove "public convenience and necessity," including:

- economic feasibility;
- financial responsibility; and
- public interest.

If the company proposes to operate over existing tracks, it is subject to "fit, willing and able" criteria that are also applied by the National Transportation Agency.

Under the *NTA, 1987*, however, a candidate passenger rail operator does not enjoy the rights of track access that apply to freight railways. We addressed this constraint on entry in Chapter 6. Of course, the presence of a heavily subsidized Crown carrier in Canada's passenger rail sector restricts the practicality of entry by others.

Entry into Canada's intercity scheduled bus industry, which is tightly regulated under public convenience and necessity criteria, is much more restrictive than the "fit, willing and able" approach would be.

Passenger ferries in Canada are not subject to restrictive economic regulation. As for all operations in Canadian waters, safety regulation under the Canadian Coast Guard includes vessel design and maintenance, and the certification of ship's officers (vessels of more than 5 gross tons require a certified master). Use of harbours and ports is subject to approval of the local authority. Imported vessels are subject to import duties (which are sometimes waived). Crown carriers dominate both the west and east coasts, and some provincially funded ferry services are provided without charge. Under such circumstances, freedom of entry does little to enhance competition.

A competitive environment is not possible where there are barriers to market entry and exit, or where government subsidies give an advantage to particular carriers or modes. For example, the carrier costs of passenger rail and ferry operators are heavily subsidized. The result is that market prices do not accurately reflect costs. In addition, such subsidies cushion passenger rail and ferry operators from the market pressures to achieve cost efficiency.

## AIR CARRIERS

For more than a decade, federal policies have been aimed at expanding the role of market forces in the airline industry. The *National Transportation Act, 1987* clearly states that market forces, rather than economic regulation, should govern the supply of air services. The NTA, 1987, however, did not remove restrictions on the foreign ownership of Canadian carriers, or on the activities of foreign-owned carriers in Canada. In addition, Air Canada and Canadian Airlines International are experiencing financial difficulties, and there are many changes taking place in the international airline industry.

In Chapter 11, we examine current government policies with respect to air travel and whether these policies protect travellers, given the major restructuring of this industry.

## RAIL CARRIERS

While there is little competition among passenger rail carriers in Canada, passenger rail does compete with other modes, particularly the bus and private car. The large contribution made by taxpayers to rail travel, however, distorts the passenger rail market. As we observed in Chapter 3 (Table 3-1), rail travellers pay, on average, only one quarter of the capital and operating costs of passenger rail service. This situation raises a number of questions, which we discuss in Chapter 12:

- Are there special considerations that apply to passenger rail service that may justify some departure from the objectives and principles we set out in Chapter 4?
- If it is desirable to eliminate the taxpayer contribution to passenger rail travel, what type of transition mechanisms are needed to give carriers and travellers a reasonable amount of time to adjust to non-subsidized operations?
- Is public ownership of passenger rail carriers desirable?
- If public ownership of passenger rail continues, what mechanisms are required to ensure that those responsible for operations are accountable for their performance?

## INTERCITY BUS CARRIERS

Intercity bus carriers in Canada are subject to provincial/territorial regulations covering pricing and entry to the market. The *National Transportation Act, 1987* did not apply to the bus industry, although it did initiate a process of regulatory reform in trucking — another industry subject to provincial/territorial economic regulation. While a few provinces, notably Alberta, New Brunswick and Prince Edward Island, have somewhat relaxed their regulations, most bus carriers operate in a more regulated market than most other transportation businesses in the economy.

We believe that it is time to critically examine the basis for the economic regulations on the intercity busing industry. In Chapter 13, we examine whether there are any special factors that distinguish this industry and that justify continued economic regulation, and, if not, what policy reforms are required.

## FERRIES

In ferries, as in passenger rail, travellers benefit from major direct taxpayer contributions to their travel on average, although — unlike passenger rail — some major ferry services come close to covering their costs. Ferry travellers cover, on average, about 60 percent of total costs, which is much higher than the 25 percent covered by rail travellers. If supply of, and demand for, ferry service solely influenced the price charged, fares would tend to be substantially higher and traffic somewhat lower.

As with other modes, we believe it is necessary to consider whether, and to what extent, taxpayers should bear some of the costs of travel by ferry passengers. It is also necessary to examine governments' relationship to the federal Crown corporation, Marine Atlantic (the main ferry operator on the east coast), and the provincial Crown corporation, BC Ferries (the main ferry operator on the west coast).

# ENDNOTES

1. See Notes to Chapter 2, Volume 2 of this report for discussion of estimate of size of private vehicle fleet.

2. This figure is based on Canadian Travel Survey data (Statistics Canada, Catalogue No. 87-504).

3. This figure is based on Royal Commission analysis (see Notes to Chapter 1 and Notes to Chapter 2, Volume 2 of this report). As noted in Chapters 1 and 2 of this report, there is a range of possible definitions of intercity travel.

# CHAPTER 11

# APPLYING THE PRINCIPLES TO AIR CARRIERS

## INTRODUCTION

In the airline industry, recent reforms have been very much in the spirit of our principles. The *National Transportation Act, 1987* largely completed the process of economic regulatory reform that began in the late 1970s for air carriers. The privatization of Air Canada during 1988 and 1989 further helped to level the playing field. As a private-sector enterprise, Air Canada now competes in the market in a similar way to other firms, neither benefiting from special preferences nor burdened by special constraints on routes or equipment.[1]

Canadian experience with the new air-carrier regulations is still limited. Some benefits are obvious, such as more flights. Poor financial performance of carriers in recent years, however, has raised concerns about the viability of the Canadian air carrier industry in the future.

## WHAT CANADIANS TOLD US

We heard opposing views on the impact of regulatory reforms in the airline industry. Some shared the position put forward in submissions by the major carriers that these reforms have been highly beneficial to Canadian travellers. For example, Canadian Airlines International Ltd. stated that "deregulation of the airline industry has resulted in greater efficiency, better service, lower prices, and balanced competition." The International Association of Machinists and Aerospace Workers, on the other hand, represented a different view: "Contrary to the promises of its proponents, transport deregulation in the United States increased concentration and lessened competition in all sectors. Our experience in Canada has closely followed the American example."

There were different responses to the issue of airline concentration. For example, proponents of the new reforms said that the industry, "after undergoing major structural changes brought on by deregulation, has finally found its equilibrium with two highly competitive national carriers which are both supported by equally competitive affiliated regional carriers" (Bernard Juteau, Air Alliance). It was emphasized to us, however, that "the survival of Canada's major carriers cannot be taken for granted" (Claude I. Taylor, Air Canada). At the same time, the Commercial Travellers' Association of Canada argued that the National Transportation Agency should promote "competition amongst airlines." Some interveners pointed to remote communities where traffic is insufficient to sustain service by more than one carrier.

The proposed open skies policy between the United States and Canada was another source of controversy. Under the current bilateral air agreement between Canada and the United States, scheduled air carriers can fly travellers only between their home country and designated destinations in the other country. They are not allowed the rights of cabotage; that is, to take on passengers within the foreign country and transport them to another destination in that country.

Some groups viewed open skies as an opportunity for improved air service between and within the two countries. Others were concerned that it would threaten the existence of Canada's major carriers. Some short-haul carriers are uncertain if they will be able to survive in an open skies environment. In addition, some warned that open skies could increase congestion and create more delays at airports.

## GOVERNMENT POLICIES OF THE PAST

Historically, Canadian air carriers did not operate under the same rules. The primary instrument of federal airline policy was the government-owned airline, Air Canada.[2] Protected against competition from private carriers, it was for many years the only Canadian transcontinental air carrier. It used the profits it earned on transcontinental and international routes to subsidize service to some smaller and more remote communities, and to comply with assorted government directives.

Canadian Pacific Airlines (CP Air) was allowed entry into the international market in 1948 and was awarded a transcontinental route in 1959 (one return flight per day), but these concessions did not allow the private carrier to become a serious competitive threat to Air Canada. Although the constraints limiting CP Air's activities on transcontinental routes were gradually relaxed after 1967, the government believed that there was a need to protect Air Canada from "undue competition."

The 1966 Regional Air Carrier Policy represented a further government effort to control the structure of the industry and to limit the degree of competition among carriers. It established one airline as the preferred carrier to provide local and regional service in each of the five regions of the country. To ensure that the regional carriers provided scheduled services that supplemented, but did not compete with, the services provided by the two national carriers, the federal air regulator was given authority to screen regional carrier purchases of aircraft. The strict regulatory policy was reasonably successful in establishing price equality between the high-cost and low-cost routes.[3]

In the late 1960s and 1970s, however, the government found it increasingly difficult to balance the demands from CP Air and the regional air carriers for less regulation with the desire to preserve Air Canada's historic role as an instrument of government policy.

This pressure coincided with public concerns about the accountability of federal Crown corporations. Of particular concern was the difficulty of monitoring the performance of Crown corporations such as Air Canada, which benefited from special concessions and were at the same time asked to meet vague objectives. The 1978 *Air Canada Act* attempted to eliminate this problem. Air Canada was now to "have due regard to sound business principles, and in particular the contemplation of profit." The following year, all constraints limiting CP Air's activities as a transcontinental carrier were removed.

The United States deregulated its airline industry in 1978, resulting in lower costs and increased service. Research in the United States, prior to 1978, had pointed to the high costs resulting from controls administered by the Civil Aeronautics Board (CAB). The studies showed that resources were being wasted because regulated prices gave carriers misleading signals about the type and quality of service to provide, and that airline costs and fares were substantially higher than they would be in an unregulated environment. In a fully competitive environment, high labour costs could not be passed on to consumers as easily as they could in a regulated market. Furthermore, an unregulated environment would give airline managers the freedom to structure their operations in the most efficient manner.

The results of deregulation in the United States generally confirmed these expectations. After the relaxation of price controls and the opening of entry, air service expanded considerably and average fares, adjusted for inflation, declined substantially under the pressure of intense carrier competition. Since the mid-1980s, a number of airline failures, acquisitions and mergers has resulted in a major restructuring of the industry. Notwithstanding the high degree of industry concentration, most airline markets are subject to competition. Recent studies found that consumers, overall, benefited substantially from deregulation — which has brought increased airline efficiency, air fares that better reflect airline costs, airline service to more locations, and more flights.[4]

After deregulation in the United States, pressures mounted to end economic regulation in Canada. The experience in the United States with deregulation highlighted the gains that a more competitive airline industry brought to consumers. In addition, deregulated U.S. carriers appeared to attract a significant share of Canadian business in some markets.[5]

Price competition in the Canadian market intensified in 1980 under the more liberal charter regulations introduced by the Canadian Transport Commission. In 1984, a new Canadian Air Policy eliminated the remnants of the Regional Air Carrier Policy, substantially eased the conditions of entry into airline markets in southern Canada, and gave carriers more freedom to set fares.

## CURRENT GOVERNMENT POLICIES

The *National Transportation Act, 1987* (NTA, 1987), which came into effect on January 1, 1988, states that "economic regulation of carriers and modes . . . will not unfairly limit the ability of any carrier or mode of transportation to compete freely with any other carrier or mode of transportation." The Act distinguishes between airline activity in southern and northern Canada.

Economic regulation of airline activity in southern Canada has been almost completely dismantled. To enter the market, a prospective carrier must simply establish that it can meet basic safety, insurance and Canadian-ownership requirements. Carriers do not require permission to exit from a market, although they must notify the National Transportation Agency 120 days in advance of their intention to reduce (to less than one flight per week) or eliminate a service that had been offered once a week or more for six months. Fares must be published, but they are not subject to regulation. There is, however, a provision that allows the public to appeal to the Agency about basic fare increases on monopoly routes. The Agency may disallow all or part of the increase if "there is no other alternative, effective, adequate and competitive transportation service," and if the increase is found to be "unreasonable." This provision, in respect to southern markets, has had, as yet, little use and no complaints have reached the formal investigation stage.

Airline activity in and to northern Canada is still subject to some economic regulation. Those objecting to the entry of a new carrier can challenge that entry, but the onus is on the opponents to demonstrate that entry would jeopardize the quality of existing services. Exit from a northern market is subject to the same advance-notice provisions as exist in southern Canada. Fares are also not regulated, but the provision for appeal is somewhat broader. Objectors may ask the Agency to investigate either an unreasonable basic fare increase or an unreasonable basic fare level. There have been a number of investigations of northern rates, but in none of these cases, since 1988, did the Agency find that the levels or increases were unreasonable.

Foreign ownership of Canadian air carriers is limited by law. The NTA, 1987 requires that at least 75 percent of the voting shares of Canadian air carriers be owned by Canadian residents, and that control of these airlines is held by Canadians.[6] In addition, ownership restrictions are incorporated in the legislation that provided for the privatization of both Air Canada and Pacific Western Airlines (PWA), the parent of CP Air, now Canadian Airlines International Ltd. The federal *Air Canada Public Participation Act* limits the holdings of any one person or group to 10 percent of voting shares, and the holdings and control of non-residents in aggregate to 25 percent of voting shares. The Alberta government's *Pacific Western Airlines Act* restricts the holdings of any one person or group to 10 percent of the voting shares, and since the *National Transportation Act, 1987* also applies to PWA, its foreign ownership and control are also restricted.[7]

## CHANGES UNDER ECONOMIC DEREGULATION

In the early 1980s, the main providers of air passenger service were:

- two transcontinental carriers — Air Canada and CP Air;
- four regional carriers — PWA, Nordair, Eastern Provincial Airways and Quebecair — that also provided scheduled jet service; and
- one charter carrier — Wardair.

In 1982, government-owned Air Canada earned two and a half times more revenue than CP Air and carried three times the number of passengers.

During the second half of the 1980s, there was a dramatic restructuring of the industry. PWA acquired CP Air in 1987 and gained control of those regional carriers that had already been absorbed into the CP Air system — Eastern Provincial Airways and Nordair. Canadian Airlines International Ltd., the new consolidated operation owned by PWA, acquired Wardair in 1989. Wardair, formerly a charter carrier, ran into financial difficulties shortly after its 1986 entry into the domestic market for scheduled service. Also in the 1980s, Air Canada acquired interests in a number of regional airlines — Air Ontario, Air BC, and NWT Air.

While these reorganizations were under way, the federal government was evaluating its own position as owner of Air Canada. By the early 1980s, the carefully designed system of cross subsidization was eroding, and it was difficult to distinguish Air Canada from private carriers. Air Canada was privatized by two share offerings — in September 1988 and July 1989.

Today, the airline industry is dominated by two large private-sector corporations, Air Canada and Canadian Airlines International (the "majors"). Both corporations have established feeder affiliates and integrated them into their operations. Integration has involved the coordination of flight timetables and the incorporation of the feeders into the baggage, reservation and frequent-flyer systems of the majors. Table 11-1 provides a snapshot of the two "airline families" as of the end of 1991.

The majors have similar shares of domestic traffic, although Air Canada continues to predominate in international markets. Independents and smaller commuter airlines not connected to the majors also provide scheduled service. In 1991, there were 288 level 1 to 4 air carriers (having annual gross revenues of $250,000 or more). Along with the majors and their affiliates, and independent scheduled carriers, level 1 to 4 carriers include charter carriers (for example, Nationair, Canada 3000 and Air Transat) that are an important source of competition on many major routes. Independent airlines enjoyed a period of growth in the 1980s, but a number of the more important independents (Intair, City Express) have failed. The majors' affiliates, however, have enjoyed strong growth as the majors have streamlined their operations and withdrawn from markets they could not profitably service with their large aircraft.

**Table 11-1**

**STRUCTURE OF THE AIRLINE "FAMILIES," 1991**

| Airline[a] | Points served | Percentage ownership by parent/ subsidiary | Fleet |
|---|---|---|---|
| Air Canada[b] | 48 | Parent | 115 jets |
| Air Nova | 16 | 100 | 5 jets; 9 non-jets |
| Air Alliance | 14 | 75 | 15 non-jets |
| Air Ontario | 10 | 75 | 21 non-jets |
| *Air BC* | 26 | 85 | 5 jets; 33 non-jets |
| Pacific Coastal Airlines | 9 | 50 | 18 non-jets |
| NWT Air[c] | 5 | 100 | 2 jets; 1 non-jet |
| PWA Corporation[d] | — | Parent | — |
| Canadian Airlines International[e] | 42 | 100 | 76 jets |
| *Canadian Regional Airlines*[f] | — | 100 | — |
| Inter-Canadien | 26 | 70 | 12 non-jets |
| Ontario Express | 25 | 100 | 26 non-jets |
| Calm Air | 22 | 45 | 8 non-jets |
| Time Air | 29 | 100 | 7 jets; 29 non-jets |
| Air Atlantic[g] | 19 | 45 | 3 jets; 13 non-jets |

Source: National Transportation Agency, *Anual Review 1991*, pp. 22-23.

a. Parent companies appear in white type. Firms indented once are owned by the parent. Firms indented twice are owned by the preceding firm in italics.

b. In April 1991, Air Canada established Air Canada Regional Airline Holdings to manage its regional carrier interests.

c. NWT Air has code-sharing agreements with five affiliated carriers (which serve 21 points).

d. PWA Corporation is a holding company and thus does not operate its own services.

e. Canadian Airlines International includes the division Canadian North, which serves 23 additional destinations in the Northwest Territories, Quebec, Manitoba, and Alberta using 8 jets.

f. Canadian Regional Airlines is a management company and therefore does not operate its own services.

g. Air Atlantic is 45 percent owned by PWA Corp., but is managed by Canadian Regional Airlines.

Under deregulation, the hub-and-spoke system replaced some direct flights. Passengers from various cities increasingly travel by spoke routes into a centralized airport — the hub — from which they take connecting flights to their destination. Hubbing consolidates traffic at a central location, allowing airlines to put more passengers on each flight. Pooling of passengers also allows airlines to provide more flights to more locations than would be possible under the alternative point-to-point system.

To take advantage of the economies of hubbing, airlines require sophisticated scheduling and passenger handling systems that enable them to move a number of aircraft through a connecting point at about the same time. A successful hubbing system also requires a large network, so that incoming flights can provide the passengers needed to achieve large passenger loads on departing flights.

The economies to be realized from a hub-and-spoke system are fewer in Canada, where the population is concentrated along the Canada–United States border, than in the United States, where the population is more dispersed. Nonetheless, the realignment of flight patterns and the integration of operations in each carrier family have supported the development of some hub-and-spoke systems in Canada.

Changes in traffic patterns have had a major impact on Canadian airports. Lester B. Pearson International Airport in Toronto, which has become Canada's major hub, experienced a 58 percent (7.9 percent average annual growth rate) increase in commercial aircraft movements between 1984 and 1990.

Similarly, Vancouver and Halifax, which emerged as important regional hubs, have also experienced greater air traffic. Hubbing results in increased demands on both air and ground facilities of an airport. At Pearson, the completion of Terminal 3 has helped the airport cope with the increase in ground traffic but, to alleviate the pressure from the growth in air traffic, air movements have been capped. The cap is 82 air movements per hour as of July 1992, up from 76. There are plans to increase the number of air traffic controllers and to expand runway capacity at Pearson, as well as at Vancouver.

## AIRLINE PERFORMANCE UNDER ECONOMIC DEREGULATION

### PRICES AND COSTS

Average air fares, adjusted for inflation, have fallen in Canada during the past decade, as shown by airline yield, which is calculated by dividing passenger revenue by passenger-kilometres. This decline (Chart 11-1) is the result of several factors: a restructuring in rates due to market pressures, which led to an elimination of the cross subsidy from long-haul to short-haul flights; an increase in long-haul flights; and an increase in the importance of discount fares (Chart 11-2).

Since regulatory reforms were introduced, air fares have come to more closely reflect airline costs. Travellers flying long distances pay less per kilometre than passengers on short-distance flights because some airline costs do not increase with distance. Costs per passenger-kilometre are also lower if an airline can spread its fixed costs over more passengers by using larger airplanes and achieving higher load factors. This benefits passengers flying on high-density routes as compared with those flying between small centres.

Discount fares are more important in some markets than in others. The proportion of travellers flying on discount fares is high in long-haul, trans-border and international markets, where competition is intense. Discount fares are also more important on flights with a high proportion of leisure (as distinct from business) travellers. Discounting is an important component of the major airlines' yield management systems.[8] Airlines have become adept at fine-tuning their use of discount fares (adjusting their number, the size of the discount and the restrictions applying to their use) so as to increase passenger loads and maximize flight revenue.

**Sources: Canada: The percentage of discount passenger-kilometres for 1983–1989 is from L. Di Piétro and G. Baldwin, "Discount Air Fares in Canada: Price Competition and Price Differentiation," in *Proceedings of the 26th Annual Meeting of the Canadian Transportation Research Forum*, May 28 to 31, 1991, p. 517; 1990 data are from Statistics Canada, *Canadian Civil Aviation 1990*, Catalogue No. 51-206, November 1991, Table 6.3, p. 31. The percentage discount off the economy fare is taken from Table 2 of the first source mentioned and from unpublished data from Statistics Canada's Fare Basis Survey.**

**United States: Air Transportation Association of America, *Air Transport: The Annual Report of the Scheduled Airline Industry* (Washington: ATA of America), various issues.**

In the United States, the decline in air fares after 1978 was made possible, in part, by the ability of the airlines to exercise greater control over their labour costs. This involved tough negotiations both to reduce wage and salary expectations of airline employees, and to eliminate those work practices that were lowering productivity. The impact of deregulation on labour markets has been less pronounced in Canada.

Increases in productivity, however, have helped to restrain labour costs. The productivity of airline workers has increased at an impressive rate during the past decade (Chart 11-3). While part of this increase must be attributed to technological improvements, also important was the lifting of economic restrictions on the activities of Canadian carriers.[9]

## QUALITY OF SERVICE

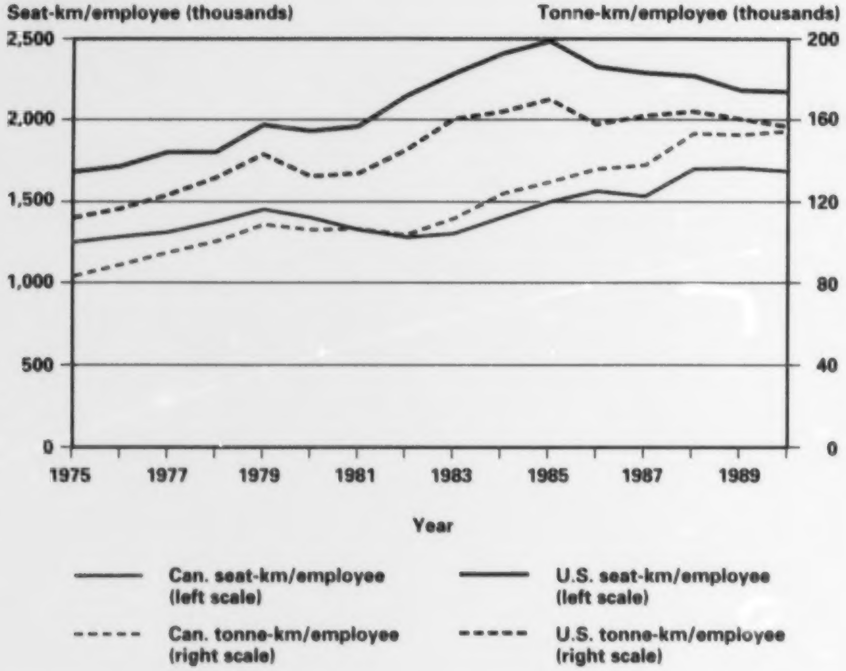
Under deregulation, carriers have the flexibility to customize services. They can provide a no-frills service for passengers who want low fares, while offering a premium service for passengers who value booking freedom and in-flight amenities.

As a result of the organizational and routing changes that have occurred under deregulation, some short-haul regional routes once served by jet aircraft are now being served by turboprop aircraft operated by an affiliate of one of the major airlines. In addition, some passengers who had been able to fly directly to their destination under the point-to-point routing system must now make connections through a hub airport. While connecting and indirect (same plane, one or more stops) services have increased, there has also been a net increase in the number of direct (non-stop) services.

Travellers now benefit from a greater choice of flights. Air services have expanded as more and more communities have become tied to one or more hub-and-spoke networks. The number of Canadian cities and towns with scheduled air service rose by approximately 60 percent between 1983 and 1990. Flight frequency also increased substantially during this period. In Canada's top 25 city-pairs, there were 51 percent more flights in 1991 than in 1983, while available seats increased by 20 percent. Researchers in the United States have

Chart 11-3

PRODUCTIVITY INDICATORS, MAJOR CANADIAN AND U.S. SCHEDULED AIRLINES, 1975–1990



**Sources:** Canada: Available seat-kilometres for 1975–1980 are from Statistics Canada, *Transcontinental and Regional Air Carrier Operations*, Catalogue No. 51-001, December issues; for 1981–1986, data are from Statistics Canada, *Air Carrier Operations in Canada*, Catalogue No. 51-002, October-December issues, Table 4; for 1987–1990, data are from Statistics Canada, *Canadian Civil Aviation*, Catalogue No. 51-206, 1988–1990 issues, Table 2.3.

Total tonne-kilometres for 1975–1981 are obtained from Statistics Canada, *Air Carrier Operations in Canada*, Catalogue No. 51-002, October-December issues; data for 1982–1990 are from Statistics Canada, *Canadian Civil Aviation*, Catalogue No. 51-206, 1982–1990 issues.

Employee statistics for 1975–1987 are from Catalogue No. 51-002; for 1988–1990, Catalogue No. 51-206, Table 4.2.

United States: Air Transport Association of America, *Air Transport: The Annual Report of the Scheduled Airline Industry* (Washington: ATA of America), various issues.

**Notes:** Canadian data refer to unit-toll services of Level 1 and Level 2 carriers for 1975–1981 and of Level 1 carriers for 1982–1990.

Seat-kilometres for regular, irregular and specific point service were estimated for 1975–1986 by applying the average load factor on scheduled services of the regional airlines. Nordair's seat-kilometres were unavailable for 1983 and 1984 and were estimated using the above method.

Tonne-kilometre statistics include both passenger and freight weights.

found that because travellers, especially business travellers, place a high value on finding flights that correspond to desired departure times, the increase in numbers of flights is one of the most important benefits of deregulation. Surveys conducted by the National Transportation Agency confirm the importance of convenient departure and arrival times to Canadian business travellers.

Air service to northern and remote communities has also increased. Regional affiliates established their own local connections to serve these markets. The result is more frequent service and links that allow travellers in these communities to connect with the country's main airline networks. The number of weekly scheduled direct flights increased by 163 percent on 60 northern air routes monitored by the National Transportation Agency between 1983 and 1991, and the number of scheduled indirect flights (same plane, one or more stops) increased by 61 percent.

There is no evidence that deregulation has lowered airline safety. Economic deregulation did not extend to safety regulation. In Canada, as in the United States, the federal government continues to set and enforce standards for safe airline operation. Opponents of deregulation believed that airlines would cut back on safety precautions because of the pressure to reduce costs and become more competitive. As we discuss more fully in Chapter 8, it is difficult to separate the effects of economic deregulation from all the other influences on air safety. Nevertheless, there is no evidence in the overall statistics on air accidents, in either Canada or the United States, that deregulation has lowered safety levels.

## MARKET STRUCTURE AND COMPETITION

In both Canada and the United States, the airline industries have become highly concentrated. In the United States, low-cost, innovative airlines that provided an important competitive stimulus in the early years of deregulation have disappeared. Today, three airlines — Delta, American and United — control more than half the market. In

Canada, the airline industry is controlled by two airlines. Air Canada and Canadian Airlines International and their networks account for approximately 95 percent of the revenue for scheduled services and 90 percent of total industry revenue. Are competitive forces in the market sufficient to impose pressure on carriers to increase efficiency and to pass on the resulting gains to consumers?

Studies of city-pair markets suggest that there has been an increase in competition. The development of the Canadian Airlines International network overcame the market imbalance that previously existed because of the dominance of Air Canada. In 1983, one carrier alone served about 20 percent of the largest communities in the country. By 1991, the two major carriers served all 43 of the largest communities that account for over 95 percent of originating and terminating traffic. Independent carriers provided scheduled service in 30 of these communities.

Consolidation in the Canadian air carrier industry, however, may not yet be over. Several charter and independent airlines have left the industry or become part of the majors' families. For example, Wardair was taken over by Pacific Western Airlines (PWA) in 1989. Intair, the largest independent, filed for bankruptcy, and its turboprop operations in Quebec were acquired by PWA in 1991.

The recent financial performance of Air Canada and Canadian Airlines International has been unimpressive (Chart 11-4). Their lower revenues are a result of several factors, including the recent economic slowdown in Canada and other countries, and the heavy debt load and high interest expenses from the purchase of $6 billion worth of aircraft since 1986. In addition, with the privatization of Air Canada and with PWA's acquisition of Wardair, both majors have had to undertake considerable re-organization.

Markets with at least two competing carriers enjoy lower fares. In the United States, it is difficult for new airlines to enter fortress hubs — those dominated by one carrier. For air travellers who cannot bypass

*Chart 11-4*
RATES OF RETURN ON INVESTMENTS FOR MAJOR CANADIAN AIRLINES, 1975–1990

**Note:** Other large carriers include CP Air, the major regional carriers and Wardair for 1975–1986 and Canadian Airlines International Ltd./Wardair thereafter.

these hubs, fares have been higher than for other travellers. In Canada, fares are higher in city-pair markets served by only one carrier, although these markets account for a small percentage of total traffic. Chart 11-5 shows that the proportion of travellers obtaining discount fares is somewhat lower in city-pair markets served by only one carrier. Chart 11-6 shows that large discounts are more common in city-pair markets served by two carriers than those served by one carrier.

Experience under deregulation has shown that the majors and their affiliates have a number of advantages over potential new entrants. Their large and well-integrated networks allow them to satisfy most

travellers' preferences for single-line service from origin to destination. Marketing innovations, particularly computer reservation systems (CRSs), but also frequent-flyer programs (FFPs) and various travel agent incentives, have also reinforced the strong position of the majors. Large carriers also have deeper pockets, and are therefore in a better position than a smaller rival to sustain the losses that sometimes result from a competitive battle. There is a debate as to whether large airlines have cost advantages over smaller airlines. It seems clear, however, that a high-volume route has lower costs than a low-volume one.

The extent of the majors' networks may make it difficult for a new airline to enter the market. Air Canada and Canadian Airlines International have been successful in bringing most feeder carriers

*Chart 11-6*

*PERCENTAGE DISCOUNT OFF ECONOMY FARE, BY NUMBER OF CARRIERS SERVING CITY-PAIRS, 1990*

into their networks. A potential carrier could have difficulty establishing itself if it could not gain access to feeder traffic. The relevant authorities must ensure that restrictive agreements between the majors and their feeders have not created a barrier preventing entry of a new carrier.

Reservations systems could also give the majors an advantage over new airlines. Air Canada and Canadian Airlines International jointly own the Gemini Computer Reservation System, which, in 1989, accounted for 82 percent of air segments (a segment being one takeoff and landing) booked in Canada. Participation in a CRS has become a necessity for airlines. Without some public monitoring, Air Canada and Canadian Airlines International could use their control of the dominant CRS system in Canada to put their potential rivals at a disadvantage.

Canada's *Competition Act* has provided a basis for addressing both the potential anti-competitive effects of CRSs and the general problem of exclusive contracts and "refusal to supply."[10] The Canadian Competition Tribunal issued rules to govern the conduct of the Gemini CRS, and an interdepartmental government committee is developing permanent regulations to be administered and enforced by the National Transportation Agency. These safeguards are adequate and appropriate.

We are firmly convinced that Canadian air travellers are better off as a result of economic regulatory reforms. Problems certainly exist under deregulation, but these should be put into perspective. Airline markets may be imperfect today, but they were even more imperfect in the past, when they were controlled by rigid economic regulations. We believe that a number of measures are available to assist in achieving the benefits of competition or to respond should competition decrease. These measures involve different elements of international air policy, to which we now turn.

## INTERNATIONAL AIR POLICY[11]

### BILATERAL AIR AGREEMENTS

International air markets are regulated through international agreements. Foreign carriers in Canada and Canadian carriers in international markets are subject to restrictions in their operations. Countries with their own domestic airlines generally do not allow foreign carriers to operate within their borders. Bilateral air agreements between countries provide a system for regulating entry and for controlling pricing, capacity, frequency and other matters in international markets. Canada's international air policy is governed by such agreements.

An objective of bilateral agreements is the sharing of air markets between the carriers of the countries involved. Moreover, the existence of bilateral air service agreements means that Canada cannot move unilaterally to deregulate international air services to and from Canada.

The international air market is tightly regulated. Canada takes part in about 60 international bilateral air agreements. Some include limits to the capacity (seats) that each country's designated airline can offer, and require both airlines to agree to any change. Some have restrictions on fares; again, the airlines must agree to the changes. The agreement with France concerning Martinique and the now-expired, experimental, trans-border agreement with the United States were the only agreements where tariff changes could be made rapidly in response to market shifts.

In agreements under which routes are operated solely by foreign carriers, Canada requires revenue sharing or other benefits to the Canadian carrier. Finally, two thirds of the agreements limit the ability of either country to designate more than one carrier on a route.

Bilateral air agreements assume that each country has at least one national airline. If there were no international Canadian air carrier, Canada would be forced to depend on foreign carriers for international airline service. The result could be a monopoly in markets to and from Canada if other countries were to assign a single national carrier to the route. For example, the Canada–France bilateral agreement allows Canadian air carriers to operate between Canada and France in competition with Air France, but does not permit Canada to designate a non-Canadian carrier for that route. In the absence of a Canadian carrier, the Canada–France market would become an Air France monopoly. Canada would have the option, however, of withdrawing from the bilateral agreement, but then Canadians wishing to travel to France would have to make their way to France via a third country.

In the context of the existing system of bilateral agreements, we want to examine the potential for Canada's international air policy to give Canadians access to competitive air services in international and domestic air markets. To achieve this, Canada requires two or more actual or potentially competing carriers operating between destinations within Canada, and between Canadian and foreign destinations.

## RECOMMENDATIONS

### OWNERSHIP AND CONTROL

Although there are no national restrictions on ownership for the other transportation modes, air carriers are protected from foreign ownership and control under the *National Transportation Act, 1987*. This protection is consistent with the Chicago Convention, which sets the requirements of the world's bilateral air agreements. Under the Chicago Convention, there must be substantial national ownership and effective control of an airline designated as national. For an airline to be a national Canadian air carrier, substantial ownership and effective control must be held by Canadians — citizens, permanent residents, a government or government agent, and entities in which Canadians own and control at least 75 percent of the voting interests or "such lesser percentage as the Governor in Council may by regulation specify."[12]

If a Canadian air carrier that flies international routes were, by virtue of foreign investment, no longer owned and under effective control by Canadians, its designation as a national airline under the relevant bilateral agreements could be challenged. This challenge could come from the remaining Canadian air carriers, the other country party to the bilateral agreement, or from carriers in competition with the newly controlled airline. Under the existing international rules, this challenge would probably succeed.

Foreign control may also affect the ability of the government to ensure the availability of domestic service in emergency situations. The *Emergencies Act* provides the Canadian government with the power to requisition the use of any equipment, which includes aircraft on Canadian territory, in times of a declared emergency. Other governments have similar laws. A foreign government might act on prior knowledge, however, and order aircraft owned, or even operated, by its nationals, to be returned to its territory (in a manner similar to the control over shipping demonstrated in the days preceding World War II).

Restricting foreign ownership and control may reduce choices to the consumer. This would be of particular concern if a situation arises where only one domestic carrier remains viable. We recognize that there are instances when a relaxation in foreign ownership controls may be necessary to preserve domestic competition (we return to this later). For the most part, though, we believe existing restrictions on foreign ownership and control of Canadian air carriers are appropriate, given the current bilateral air agreement regime.

Therefore, we **recommend** that:

**11.1 The federal government retain the existing limits on foreign ownership and control of air carriers.**

Canada also restricts individual ownership of air carriers. These restrictions ensure that shares in the air carriers remain widely held and that control by current management is preserved. We believe that such restrictions are undesirable. The unrestricted trading of shares exerts an important check on corporate management. In equity markets that function well, excellent management is more likely because badly managed companies are more easily taken over.

Therefore, we **recommend** that:

---

**11.2 The 10 percent ceiling on individual holdings, which currently applies to Air Canada and Pacific Western Airlines (the parent of Canadian Airlines International), be eliminated.**

---

## CONSOLIDATION OF THE INDUSTRY

Since we commenced our studies, dramatic changes have occurred in the airline industry. As we move through this decade and into the 21st century, the number of international carriers may well shrink, and changes will continue. These changes will have a profound effect on Canada's carriers and domestic airline services. As well, Canadian air carriers will face more formidable competition in their international operations.

The world's airlines are undergoing major restructuring. In part, this restructuring has taken the form of a shift toward partial or full private ownership of several airlines that were previously government-owned. In addition, a severe recession in North America has hastened the collapse of several U.S. carriers, resulting in the emergence of three super-carriers in that country. Through inter-carrier equity investment and the sharing of resources, management, labour, equipment and bases, several more super-carriers will likely emerge worldwide.

It is well to remember, however, that there are over 200 member airlines in the International Air Transport Association (IATA), and that many of these companies will continue providing essential services throughout the world. Will Canada's national carriers be included in this group? We believe that they will as long as their vision takes into account new pressures, challenges and opportunities.

It is possible that Canadian carriers will be able to operate successfully as independent carriers in the new mega-carrier world. On the other hand, they could become pivotal partners of one of seven or eight world-scale airlines. The outcome for Canadian air carriers — between these two possibilities — will depend on the evolution of national, continental and world markets, as well as improvements in technology, but, above all else, on their ability to be competitive, to change, to improvise, to find a special role, and to provide superior service.

We are optimistic that Canadian air carriers will have the realistic and creative energies to meet this challenge as Canada enters the 21st century.

We have considered the arguments of those who believe that the Canadian market can sustain only one major carrier, and that a merger of Air Canada and Canadian Airlines International is desirable. In 1989, the airline resulting from such a merger would have ranked 11th out of the top 50 airlines in the world in both passengers and passenger-kilometres. The advantage of such a merger is that the resulting carrier would carry more passengers and could thereby incur lower operating costs per passenger. The disadvantage of a merger is that, despite the freedom of other carriers to enter the market, domestic air transportation could become dominated, once again, by a single carrier monopoly.

We believe that the federal government should not attempt to restructure the airline industry. Rather, government policy should permit Canadian air carriers to increase their efficiency and to develop whatever market niche they can most effectively fill in the evolving airline industry.

To this effect, we **recommend** that:

---

**11.3 The federal government invite Canadian air carriers to make public proposals for future international air route designations, with the airline offering the best package to be granted the route and the reasons to be made public.**

---

Further, we **recommend** that:

**11.4 Canadian air carriers be allowed to sell designated international air routes to one another.**

Given our view that carriers will make the required adjustments toward efficiency and market niches without interference or assistance, we **recommend** that:

**11.5 Governments abstain from making any financial contribution that is intended to ensure the survival of air carriers.**

This recommendation, of course, does not preclude purchase by governments of designated services on market terms. The federal government should be prepared, however, to prevent a situation that would require a return to economic regulation, which would be the likely outcome if only one major Canadian air carrier emerges. At the time of writing, discussions were under way regarding a potential merger between Air Canada and Canadian Airlines International. The presence of only one major airline in the domestic market is inadvisable. While we are concerned with the survival of the airline companies, our overriding policy consideration is to maintain competition between at least two air carriers. We believe that Canadian travellers will be best served if there are two or more major competing carriers in Canadian skies. Maintaining competition should be the overriding policy consideration.

Therefore, we **recommend** that:

---

**11.6 If faced with a potential reduction to only one major Canadian air carrier, the federal government exercise its authority under sections 67, 72 and 73 of the *National Transportation Act, 1987* to override limitations on foreign ownership and control for the explicit purpose of, and to the extent required for, ensuring competition in the domestic market.**

---

## OPEN SKIES

The term "open skies" has been used to indicate a considerable opening of the United States–Canada border to flights to and from both countries. Increasing trade and visitor traffic have put pressure on both countries to renegotiate the United States–Canada bilateral air treaty.

There has been much discussion in the media over the past few years about the concept of open skies, in particular with the United States. One version of open skies would mean a continental free market for airlines. Carriers from each country would be allowed to fly any routes in either country. This would specifically include cabotage rights where airlines of both countries are permitted to transport travellers from one destination in the other country to another destination in that same country.

At our hearings, it was apparent that, other than representatives of airlines and a few others with closely related interests, members of the public generally were not talking about this version of open skies. What they did want, and strongly argued for, was direct service from their communities to additional destinations in the United States.

Canadians are interested in better access to foreign airline networks. They want more and better air service. This presents a real problem in negotiating a sound bilateral agreement with the United States that will meet the wishes of Canadian consumers and at the same time preserve the viability of Canada's two major carriers.

Equality of opportunity and equality of benefits for Canada's airlines are almost impossible to attain. To counteract the current dominance of U.S. carriers flying into major Canadian cities, Canadian carriers must be given the same access to all major U.S. cities, with guarantees of slots and gates. This might more accurately be termed an "open borders" policy, or "point-to-point" open skies. Under this arrangement, cross-border access would be eased considerably and Canadian consumers would get the additional service they have been demanding. U.S. airlines would benefit by adding new Canadian spokes to their hubs in the northern United States. Canadian air carriers could create Canadian hubs that would add spokes to the United States. Canadian firms would still retain all domestic flights and their international connections.

While we are in favour of open borders, we believe that Canadian carriers will require some time to prepare to meet the expected U.S. competition, which will likely concentrate on one or more of the three major centres, Vancouver, Toronto and Montreal. This period need not be prolonged. Canadian carriers must be prepared, as soon as possible, to meet this and other challenges developing worldwide. It is also well to remember that the Canada–United States Free Trade Agreement is being phased in over 10 years.

Canadians also want one or more Canadian airlines. We believe that the interests of the nation and of Canadian travellers will be best served if there are two or more major competing Canadian carriers. This should be a primary policy consideration in the renegotiation of the United States–Canada Bilateral Air Treaty.

If easing the restrictions on access to the Canadian air market and relaxing foreign ownership limits are not sufficient to maintain two major Canadian carriers, then the availability of competing services should continue to be the overriding consideration. In this event, Canada should seriously consider ways and means to ensure competition on domestic routes. This would entail one or more of the following:

- favouring alliances between Canadian and foreign carriers;
- favouring easier access for new entrants to terminals and landing slots; or
- relying on the Bureau of Competition Policy if there is abuse of monopoly power.

If all efforts to create domestic competition fail, we would recommend that the federal government consider opening up certain domestic routes to foreign airlines.

# ENDNOTES

1. Both Air Canada and Pacific Western Airlines (PWA) are subject to restrictions — including ownership restrictions and head office location — under their respective Acts.

2. Air Canada was created in 1937 but was called Trans-Canada Airlines until 1965.

3. By contrast, regulations administered in the United States by the Civil Aeronautics Board (CAB) did not afford the trunk carriers the protection they required to carry out an effective program of internal subsidization. (Many of the major routes were served by more than one trunk carrier.) U.S. carriers could not engage in price competition since the CAB regulated the level and structure of fares. But they could compete by increasing flight frequency, improving the comfort of aircraft and offering in-flight amenities. This non-price competition, which occurred in long-haul markets, ultimately eliminated the surplus that was necessary to sustain service on unprofitable routes.

4. For example, a recent review of available research on U.S. deregulation concludes:

   "At the outset of deregulation only about 20 percent of city-pair markets had three or more competitors; this share has grown to 40 percent. City-pair markets with three or more competitors serve about two-thirds of passenger trips. To date, this competition has generated many benefits for consumers. The freedom given to managers by deregulation to realign their routes and costs has resulted in a more efficient industry. Average fares have increased more slowly than costs, although most bargains occur in markets in which three or more carriers compete for service, especially when one of those competitors is a low-cost, new-entrant airline. The development of hub-and-spoke networks, spurred by deregulation, has expanded the frequency and availability of service in most parts of the country. In addition, rural areas, which used to receive subsidized jet-carrier service, continue to receive air service, though now via smaller turboprop aircraft. Substantial improvements in the frequency and timeliness of service have occurred in most rural areas. Even while the industry has evolved and service has expanded, accident and fatal accident rates have been lower than during the period before deregulation."

   Transportation Research Board, National Research Council, *Winds of Change: Domestic Air Transport Since Deregulation* (Washington, D.C., 1991), Special Report 230, p. 2.

5. There is anecdotal evidence of Canadians driving several hours to take advantage of substantially lower U.S. airfares on international and transcontinental flights and other flights to U.S. destinations.

6. "Canadian" includes Canadian citizens, permanent residents within the meaning of the *Immigration Act*, a government or government agent, and entities that are 75 percent controlled by Canadians.

7. The *Pacific Western Airlines Act* was recently amended. The previous provision regarding holdings restricted the holdings of any one person or group to 4 percent of the voting shares.

8. The objective of yield-management systems is to maximize revenues by, in part, minimizing the number of empty seats on flights. Computer programs allow the airlines to predict the number of empty seats on each flight and to determine the nature of the discounts that are required to attract sufficient new passengers to achieve full capacity. The yield-management system will also help airlines determine the nature of the restrictions or discount fares (such as advanced booking, advanced purchase, minimum and maximum stay, no cancellation) required to reduce the diversion of potential full-fare passengers to

discount fares. The computer keeps a running check on actual bookings compared with expected bookings on each flight and flags those flights for which there is a need to attract additional passengers or make other adjustments.

9. Changes in revenue tonne-kilometres per employee reflect changes in load factor, and hence capture the results of the innovations in load management discussed above. They also incorporate the effect of efforts to increase seat-km per employee; using this latter measure, labour productivity increased by 3.4 percent annually between 1984 and 1990, compared with only 0.4 percent annually between 1975 and 1983.

10. The *Competition Act* provides for a remedial solution when competition is precluded because someone is withholding an essential input. In these circumstances, the Competition Tribunal can order that the required input be made available to the aspiring competitor on the usual trade terms.

11. Air transportation to, from and within Canada accounts for slightly more than 2 percent of all global air markets. The mix of domestic and international passenger traffic varies considerably from one country to another. The United States has a low proportion of international service, about 24 percent, while the United Kingdom's carriers depend on international traffic for 97 percent of their revenue.

    For Canada, the mix is more balanced. In 1990, Canadian carriers, scheduled and charter together, carried some 37 million passengers, of which approximately 65 percent travelled between domestic and international destinations. Travel to and from the United States (measured by number of one-way trips) was 50 percent of Canada's total international market.

    The report of a task force established by the Minister of Transport to review Canada's international aviation policy to prepare for emerging global trade and travel patterns, published in January 1992, provides more detailed information on the importance of the Canada–United States trans-border air market and overseas markets.

12. This is the definition of "Canadian" under section 67(1) of the *National Transportation Act, 1987*.

# CHAPTER 12

# APPLYING THE PRINCIPLES TO RAIL CARRIERS

## INTRODUCTION

In this chapter we review the rail industry in Canada, the railway companies that provide intercity, remote access, tourist and extended commuter services and the views Canadians expressed to us on passenger rail issues.

We then undertake a more detailed examination of the operations, financial performance and future prospects of VIA Rail, including a comparison of VIA Rail with Amtrak, the United States' national passenger rail service. We conclude this section with our recommendations for the main passenger rail operations and for remote rail services.

We then consider the issues raised by proposals for new high-speed rail services, and make recommendations about how to approach high-speed rail decisions.

## THE PASSENGER RAIL INDUSTRY IN CANADA

In Canada, passenger rail's share of the intercity travel market has declined. As in Europe and the United States, where car travel predominates and air travel has increased substantially for longer trips, the share of rail travel has declined and rail is now used primarily for shorter trips.

VIA Rail accounts for more than 90 percent of intercity passenger rail travel in Canada. VIA Rail inherited most of the nation's passenger rail operations by the late 1970s, when the federal government relieved Canadian National Railways (CN) and Canadian Pacific Ltd. (CP) of the responsibility for these services. Unlike the passenger railways of other countries, including Amtrak in the United States, VIA Rail does not own large quantities of track, but rents track from the freight railways.

Other railways also provide intercity passenger services in Canada. The Ontario Northland Railway (ONR) is provincially owned. It provides service six days a week between Toronto and Cochrane (776 kilometres), and, three days a week, a mixed freight and passenger train service in the remote area between Cochrane and Moosonee (300 kilometres). The ONR also provides daily tour service between Cochrane and Moosonee during the summer.

The Ontario government's subsidy for ONR includes capital financing and approximately $15 million annually for operating expenses. The $15 million includes a federal subsidy ($2 million in 1989) paid through CN and the ONR to the government of Ontario for the Toronto to North Bay part of the Cochrane service.

The Algoma Central Railway (ACR) provides service between Sault Ste. Marie and Hearst (476 kilometres) six days per week during summer and three days per week during winter. Most of this route is without road access. Algoma Central Railway also operates tours on this route that account for the majority of its passenger revenues. During the 1980s, ACR received $15 million under the terms of a joint federal-provincial agreement. In addition, federal taxpayers pay approximately $2.5 million per year for this service.

The provincially owned British Columbia Railway (BCR) offers daily service between North Vancouver and Lillooet (254 kilometres). Trains continue through to Prince George (490 kilometres) three days per week and daily during the peak season. Over half of the ridership consists of tour groups. British Columbia taxpayers provide approximately $3 million a year for operations, with separate funding for the purchase and upgrading of passenger equipment as required.

The Quebec North Shore and Labrador Railway (QNS&L) provides twice-weekly mixed train service from Sept-Iles to the Schefferville–Labrador City area (about 600 kilometres through an area without road access). The federal government pays approximately $1 million in annual subsidies for this service.

Ontario's GO Transit and the Montreal commuter services provide shorter distance intercity services, and there are small tourist services in the Yukon Territory, Alberta, Ontario, Quebec and New Brunswick. Also, Rocky Mountaineer Rail Tours, a private-sector company, operates two routes: one between Vancouver and Calgary, through Banff, and the other between Vancouver and Jasper. Rocky Mountaineer Rail Tours receives no subsidy.

Amtrak offers daily trains between Toronto and Chicago, via Sarnia, and between Toronto and New York, via Niagara Falls. Amtrak's Toronto trains, which carry passengers between cities within Canada, are operated by VIA Rail and subsidized as part of the VIA Rail network. There are no Canadian subsidies for Amtrak's two services between Montreal and New York or Washington, D.C., since they do not carry passengers from point to point within Canada.

Most passenger rail services in Canada are subsidized (Table 12-1). Federal taxpayers cover 100 percent of VIA Rail's losses and 80 percent of the losses for federally chartered carriers required to provide passenger rail services. Provincial taxpayers pay for losses incurred by provincially owned railways. Although passenger rail systems in most other countries recover a somewhat greater percentage of their costs than does VIA Rail, they are government-owned and operated and require substantial taxpayer support in terms of funding.

*Table 12-1*

*DIRECT GOVERNMENT SUBSIDIES PAID FOR PASSENGER SERVICES IN CANADA, 1987*[a]

| Company | Operating subsidy ($ millions) | Passengers ($ thousands) | Passenger-km ($ millions) | Revenue per passenger-km (¢) | Subsidy per passenger-km (¢) |
|---|---|---|---|---|---|
| VIA Rail | 499.0 | 5,865.0 | 2,092.6 | 9 | 24 |
| BCR | 2.5 | 78.9 | 18.2 | 9 | 14 |
| ONR | 16.1 | 132.4 | 53.6 | 8 | 30 |
| ACR | 2.3 | 39.8 | 9.0 | 10 | 26 |
| QNS&L | 1.0 | 18.7 | 5.4 | n/a | 18 |

**Source: Information from carriers.**

**a. Amounts are approximate. In addition, there were losses and capital contributions borne by shareholders (including governments) or cross-subsidized by the freight traffic.**

## WHAT CANADIANS TOLD US

By far, the majority of people who appeared at our public hearings spoke about passenger rail service. The views on passenger rail were the most strongly held views that we heard. There was a belief among most interveners that passenger rail had served Canadians well in the past, that it was necessary for the future, and that it was faltering today because it had not been given a fair chance by the federal government.

Canadians' reasons for supporting passenger rail vary. Rail support groups and environmental groups argued that rail is the most environmentally friendly mode of travel, and is also the safest and most accessible mode of travel. Some local governments, especially in regions whose services were cut in 1990, saw passenger rail service as vital to their local economies. The tourism industry noted passenger rail's value in attracting foreign visitors. Unions argued for the necessity of preserving existing rail jobs. Still others argued, especially in the case of new high-speed train technology, that greater investment in passenger rail service will provide a general boost to the economy.

Many Canadians see rail service as a right. They made the point that rail had played a key role in building Canada, and continues to play a role in holding the country together. Those who had been directly affected by the VIA Rail cuts often expressed outrage at what they saw as the loss of an important transportation option. Even communities that had not been served by passenger rail for many years called on the federal government to reinstate VIA Rail services.

Many interveners felt that passenger rail had been set up to fail and that the solution lies in fixing VIA Rail. Many supporters of rail, and VIA Rail itself, argued that rail service cannot succeed until VIA Rail is given the freedom to manage without federal government interference. Rail unions stated that VIA Rail had been mismanaged from the beginning. Some groups, such as the Western Rail Passenger Restoration Committee, suggested that VIA Rail would be much better off if it were modelled after Amtrak. One widely expressed view was that an infusion of capital would allow VIA Rail to succeed, and that this expenditure would be justified because governments in Canada now subsidize the other modes of passenger travel. Few interveners suggested how Canadians could pay for passenger rail service if its potential ridership would not support it.

Other interveners pointed to high-speed rail service in Europe as an example of how passenger rail can be successful. It was suggested that, in addition to passenger transportation benefits, a high-speed rail project in the Toronto to Montreal corridor would boost the economies of both Ontario and Quebec. Few interveners felt that high-speed rail could succeed without taxpayer help — at least in providing the necessary infrastructure.

## VIA RAIL

### FINANCIAL PICTURE

During the 1980s, VIA Rail's passenger volume and average trip length declined. Table 12-2 shows VIA Rail's financial and operational performance from 1980 through 1991. Annual passenger volume dropped from 7.6 million in 1980 to 6.5 million by 1989, and passenger-kilometres dropped from 3,104 million to 2,442 million in the same period, reflecting shorter average trip lengths. The 1990 and 1991 figures reflect the cuts to service in January 1990, and those for 1990 include some costs associated with the transition to less service.

*Table 12-2*
*VIA Rail: Financial and Operational Results, 1980–1991*

| **Results** | **Year** | | | | | | |
|---|---|---|---|---|---|---|---|
| | **1980** | **1983** | **1986** | **1988** | **1989** | **1990** | **1991** |
| Passengers (thousands) | 7,586 | 6,541 | 6,286 | 6,415 | 6,457 | 3,536 | 3,633 |
| Passenger-km (millions) | 3,104 | 2,411 | 2,261 | 2,299 | 2,442 | 1,263 | 1,320 |
| Operating deficit per passenger-km (¢) | 10 | 19 | 21 | 25 | 22 | 31 | 28 |
| Total subsidy ($ millions) | 408 | 598 | 506 | 637 | 532 | 382[b] | 368[c] |
| Subsidy (percent)[a] | 74 | 75 | 71 | 74 | 68 | 73 | 71 |

**Source: VIA Rail annual reports and corporate plan summaries.**

**a. Government funding, including capital funding, as a percent of total expenditures.**
**b. Does not include $60 million for network restructuring.**
**c. Does not include $25 million for network restructuring.**

VIA Rail's subsidy grew from $408 million in 1980 to $637 million in 1988. After the federal government cut routes in 1990, the subsidy fell to $382 million. Adjusted for inflation, the increase prior to the VIA Rail cuts was small — only 5 percent in 10 years. Despite an increase in revenues, the operating deficit per passenger-kilometre (adjusted for inflation) increased by 27 percent.

From its inception through 1991, VIA Rail cost Canadian taxpayers $5.6 billion in operating losses and $1.2 billion in capital expenditures — for a total of $6.8 billion in subsidies.

## SERVICES AND COSTS

In 1989, before the cutbacks, VIA Rail offered more than 35 different passenger rail services. We have grouped the non-remote services as follows:[1]

- Toronto–Ottawa–Montreal (Tor–Ott–Mtl);
- Southwestern Ontario (SO);
- Western Transcontinental (WT), Vancouver to Toronto;
- Eastern Interprovincial (EI), between Montreal and the Maritimes; and
- Regional, Maritime and others.

Could VIA Rail's services recover more of their costs in the future and become self-sufficient? To answer this question, we examined non-remote service groupings, including services terminated in January 1990. We considered a scenario (Table 12-3) in which VIA Rail increased ridership, raised fares and brought in greater revenues. We adjusted VIA Rail's recent actual service costs to reflect anticipated improvements that could result from better labour practices, modern equipment and reduced overhead costs. For example, we assumed engine and train crew reductions for certain services. In addition, we reduced equipment maintenance costs to reflect anticipated economies from recent and planned equipment investment and renovation.

As far as was feasible, we used the same financial parameters in our calculations for passenger rail as were used for the other modes. We included depreciation and interest on the investment in passenger locomotives and cars, and the costs of using the track are included as these are direct payments by VIA Rail to the track owners. We did not include full capital charges for the investment in stations, maintenance shops and other publicly provided infrastructure; therefore, VIA's costs are slightly underestimated.

Even with the assumed improvements shown in Table 12-3, no VIA Rail service could recover its costs without steep price increases. Modernized, efficient equipment, improvements in crewing practices, and other economies would reduce the cost of passenger rail operations. The result, shown in Table 12-3, would be a major improvement in VIA Rail's cost recovery and, consequently, a significant reduction in subsidies from Canadian taxpayers. Such economies, however, would not result in any of the services approaching self-sufficiency.

*Table 12-3*
*VIA Rail Services — Adjusted for Anticipated Improvements, $1990*[a]

| | Tor-Ott-Mtl | SO | WT | EI | Maritime Regional |
|---|---|---|---|---|---|
| Annual passengers (thousands) | 2,004 | 1,326 | 202 | 297 | 275 |
| Average trip length (km) | 351 | 183 | 1,430 | 716 | 229 |
| Load factor (percent) | 70 | 47 | 79 | 64 | 36 |
| Passenger-km/train-km | 191 | 122 | 158 | 183 | 43 |
| Revenue ($ millions) | 76 | 31 | 31 | 19 | 5 |
| Revenue per passenger-km (¢) | 11 | 13 | 11 | 9 | 8 |
| Costs of operations ($ millions) | 83 | 44 | 63 | 45 | 14 |
| Customer service ($ millions) | 31 | 18 | 12 | 10 | 4 |
| Administration ($ millions) | 13 | 7 | 8 | 6 | 2 |
| Capital charges ($ millions) | 20 | 15 | 20 | 20 | 5 |
| **Total costs ($ millions)** | **146** | **84** | **103** | **81** | **25** |
| Deficit ($ millions) | 70 | 54 | 72 | 62 | 20 |
| Cost recovery (percent) | 52 | 36 | 30 | 24 | 20 |
| Subsidy (percent) | 48 | 64 | 70 | 76 | 80 |
| Deficit per passenger ($) | 35 | 40 | 356 | 209 | 73 |
| Deficit per passenger-km (¢) | 10 | 22 | 25 | 29 | 32 |

**Source: Royal Commission staff estimates from data provided by VIA Rail.**

[a] **Where available, 1990 data were adjusted for assumed improvements in costs, ridership and revenues (see text). The "Maritime Regional" column is based on data for VIA Rail's (pre-cuts) 1989 Maritime regional services with similar adjustments. Totals do not always add up due to rounding.**

Most VIA Rail services discontinued in 1990 had particularly low cost recovery. The routes included in the Maritime Regional services column of Table 12-3 were discontinued. Even allowing for reasonable improvement in both costs and revenues, these services would remain far from recovering operating costs.

VIA Rail's remote services have declining ridership and high costs. The federal government contracts with VIA Rail to operate eight mandatory services that include remote locations without access to all-weather roads. A ninth is serviced by the Vancouver to Toronto train. Ridership on remote services is shown in Table 12-4. Demand for these services has been declining, while costs have been increasing. The estimates of the costs to taxpayers of VIA Rail's mandatory services are shown in Table 12-5.

*Table 12-4*

*MANDATORY SERVICES ANNUAL RIDERSHIP, 1985–1990*[a]

| Route | Year | | | | | |
|---|---|---|---|---|---|---|
| | 1985 | 1986 | 1987 | 1988 | 1989 | 1990 |
| Prince Rupert–Jasper | 23,334 | 29,712 | 26,817 | 26,665 | 27,171 | 16,766 |
| Winnipeg–Churchill | 57,493 | 50,334 | 52,009 | 48,847 | 44,298 | 30,446 |
| The Pas–Lynn Lake | 11,616 | 9,156 | 8,660 | 8,871 | 7,679 | 8,603 |
| Wabowden–Churchill | 1,631 | 1,041 | 962 | 797 | 399 | 210 |
| Winnipeg–Capreol | 71,643 | 65,057 | 54,616 | 54,101 | 48,479 | b |
| White River–Sudbury | 8,598 | 10,423 | 9,590 | 10,195 | 9,805 | 4,715 |
| Cochrane–Senneterre | 6,815 | 5,997 | 5,329 | 5,043 | 4,293 | 1,591 |
| Senneterre–Montreal | 54,615 | 50,798 | 42,979 | 43,197 | 38,131 | 21,759 |
| Jonquiere–Montreal | 37,295 | 34,416 | 31,350 | 31,400 | 27,248 | 11,937 |

Source: Data provided by Transport Canada.

a. Includes traffic handlings to non-remote segments of routes.

b. Service to remote area provided by Vancouver–Toronto train since 1990.

There is little potential to improve cost recovery for the mandatory services by increasing revenues. Even a doubling or tripling of fares would have only a minor effect on losses. To reduce subsidies, the costs of providing mandatory services would have to be considerably reduced. VIA Rail could achieve this cost reduction if it limited services to truly remote areas. We do not believe that it is sensible to massively subsidize hundreds of kilometres of passenger railway service in areas where there are parallel road and bus services, and, in some cases, air services.

*Table 12-5*
*MANDATORY SERVICES COST RECOVERY, 1990*

| **Route** | **Total subsidy ($000)** | **Recovery ratio (%)** | **Subsidy per passenger-kilometre ($)** |

## COMPARING VIA RAIL WITH AMTRAK

The passenger rail systems of most other countries would not, generally, serve as useful comparisons with Canada's passenger rail services. In Western Europe, rail is used primarily for passengers, with freight being a secondary activity. The opposite is true for Canada. The geography of Europe, with large, densely populated cities in close proximity to each other helps to make train travel preferable to air travel between population centres.

Amtrak operates in a geographic and cultural environment somewhat like that of Canada. Distances between cities in the United States are large, and most Americans prefer car and air travel to passenger rail.

Amtrak's percentage of cost recovery has improved steadily. Table 12-6 shows that Amtrak has had decreasing deficits and subsidies since 1983. Officials from Amtrak state that operating deficits will disappear by the end of the century, but that the government must continue to provide a capital subsidy.

*Table 12-6*

*AMTRAK: FINANCIAL AND OPERATIONAL RESULTS, 1983–1989*

| Results | Year | | | | | | |
|---|---|---|---|---|---|---|---|
| | 1983 | 1984 | 1985 | 1986 | 1987 | 1988 | 1989 |
| Passengers (millions) | 18.9 | 19.5 | 20.8 | 20.3 | 20.4 | 21.5 | 21.4 |
| Passenger-km (millions) | 6,807 | 7,127 | 7,768 | 8,071 | 8,406 | 9,142 | 9,433 |
| Operating deficit per passenger-km (¢) | 12 | 13 | 10 | 08 | 08 | 07 | 07 |
| Total subsidy ($ millions) | 977 | 980 | 935 | 776 | 774 | 644 | 619 |
| Subsidy (percent)[a] | 60 | 57 | 54 | 48 | 45 | 37 | 33 |

**Source: Royal Commission staff calculations based on data from Amtrak annual reports.**

**a. Government funding as a percentage of total expenditures.**

Why is Amtrak's performance better than that of VIA Rail? We identified a number of reasons why Amtrak is enjoying lower deficits and better cost recovery. To start with:

- Amtrak uses up-to-date, efficient rail equipment.
- Amtrak's labour practices permit higher productivity than VIA Rail's.
- Amtrak has a more favourable formula than VIA Rail for paying the freight railways for use of their track, although the difference only accounts for a 1 to 2 percent difference in total costs.
- From the beginning, VIA Rail had less freedom to make decisions due to the lack of a legislated mandate. Unlike Amtrak, VIA Rail was forced to take over all routes previously served, whereas the least viable U.S. routes were discontinued before Amtrak took over.
- In 1989, Amtrak had $400 million in general revenue from non-intercity passenger rail business such as commuter services, from equipment maintenance services, from charges to freight railways for use of its track in the northeast corridor of the United States and from carrying mail.

But these reasons do not explain all the differences between VIA Rail's and Amtrak's performance. Some of the remaining difference lies in the nature of the services offered by each company.

VIA Rail offers more services relative to population size. Before comparing individual services, we note that, even after the 1990 service cuts, VIA Rail still provides about 30 percent more passenger-kilometres of service per Canadian than Amtrak does per American. VIA Rail also has about three times the length of route network per capita. Thus, the average number of riders on VIA Rail per kilometre is lower than that of Amtrak, and VIA Rail has many more routes with very low ridership. Amtrak has no services with fewer than 40,000 passengers per route-kilometre, whereas VIA Rail, even after the 1990 cuts, has several such services (Chart 12-1).

Chart 12-2 shows the operating cost-recovery ratio for selected Amtrak and VIA Rail services. To improve comparability we have excluded Amtrak's Metroliner service between New York and Washington, D.C., services where the average passenger travels less than 100 kilometres, and services where sleeping accommodation is provided. As Chart 12-2 demonstrates, VIA Rail's lowest density services, some of which were eliminated in 1990, have very poor cost recovery and few services recover their operating costs.

Cost recovery for VIA Rail would be improved by eliminating more of the less-used services, and improving service and increasing fares on the high-use routes. This strategy was adopted for Amtrak at its outset.

Some Amtrak services are similar in density and length to some VIA Rail services in the Windsor to Quebec City corridor. In some cases, their cost-recovery rates are also similar; in others, Amtrak's cost recovery is better for various reasons.

Chart 12-1

AMTRAK AND VIA RAIL SERVICES: DENSITY VERSUS AVERAGE TRIP LENGTH, 1989

### EXAMPLES OF COMPARABLE VIA RAIL AND AMTRAK ROUTES AND THEIR RATES OF OPERATING-COST RECOVERY

| | | | |
|---|---|---|---|
| **1)** | **VIA Rail:** | **London–Toronto** | **53%** |
| | **Amtrak:** | **Milwaukee–Chicago** | **55%** |
| | | **Harrisburg–Philadelphia** | **41%** |

**This similarity in cost recovery indicates that, for certain kinds of routes, VIA Rail can equal Amtrak's financial performance.**

| | | | |
|---|---|---|---|
| **2)** | **VIA Rail:** | **Montreal–Quebec City** | **46%** |
| | **Amtrak:** | **Oakland–Bakersfield** | **67%** |

**In this case, the Oakland–Bakersfield route benefits from a substantial capital contribution from the state of California.**

| | | | |
|---|---|---|---|
| **3)** | **VIA Rail:** | **Toronto–Ottawa** | **69%** |
| | **Amtrak:** | **Niagara Falls–New York** | **98%** |

**Amtrak's high cost-recovery rate on the Niagara Falls–New York route can be attributed, in part, to high-performance turbo trains, whose capital costs are not reflected in Amtrak's figures.**

Unlike Amtrak, VIA Rail has no specific founding legislation. VIA Rail is accountable to the Minister of Transport for providing specified services in exchange for specified payments under the terms of an annual confidential contract. Transport Canada negotiates the terms of the contract and monitors performance. The Minister must approve any departure from the specifications in the contract. The National Transportation Agency has the power to regulate some aspects of VIA Rail's fares, and the federal government approves VIA Rail's operating and capital budgets.

Amtrak, on the other hand, was created by an Act of Congress, and is dependent for its operating deficit and capital funding on appropriation bills passed by Congress. Amtrak must answer to Congress regarding the financial performance of the corporation, and to individual members where its activities are of local interest. The corporation is accountable to the Federal Railroad Administration for safety matters only.

Amtrak's superior financial performance can be partially explained by differences between U.S. and Canadian markets, different accounting treatments and arrangements for payment for access to the track, greater renewal (at taxpayers' expense) of rolling stock, and assets that generate revenue from sources other than intercity railway passengers.

Representatives from VIA Rail, and others concerned about its future, told us that VIA Rail has been hindered by lack of a clear mandate and the authority to manage its own affairs. While we believe that the poor financial performance of Canada's passenger rail system is predominantly due to factors beyond any management's control, we agree that federal government involvement in investment and operations has worsened an already difficult financial situation.

## THE FUTURE OF VIA RAIL

Investing in new equipment would reduce VIA Rail's operating costs. The Minister of Transport's (1985) Task Force[2] stated that new equipment and modernization would be necessary if VIA Rail were to provide effective passenger rail service and to control its deficits. VIA Rail is currently rebuilding 1955-vintage cars at a cost in excess of $1 million per car, as well as completing a program of upgrading track, equipment, maintenance facilities and stations.

We recognize that VIA Rail's operating costs could be reduced and ridership improved by rebuilding or replacing equipment. Investment in new equipment, however, must be based on more than shifting deficits from the operating accounts to the capital account. Governments must decide whether VIA Rail should continue providing current services, or even continue as an entity, before undertaking any new long-term capital investments.

Heavily subsidized passenger rail is detrimental to competition with other modes. The principles of equal treatment and fair competition in our recommendations would be violated if a subsidized rail service continued to compete with non-subsidized modes that must face full market pressures. VIA Rail's presence with a subsidy in the market gives it an unfair advantage over both the air and the bus industries. Price competition is especially acute in the region between Windsor and Quebec City, where [illegible], air carriers and VIA Rail often operate parallel services.

We are also concerned that under-priced rail services might be overused relative to other goods and services in all sectors of the economy, including other modes of passenger transportation. Although the effect may not be substantial in the VIA Rail case, artificially underpriced transportation generally leads to inefficient decisions about travel and the way Canadians choose residential, business and recreational locations.

Fares based on full cost recovery would greatly increase the price of train travel. Full cost-recovery fares between Toronto and Montreal for one-way travel would average over $120, more than double the present average. For other VIA Rail routes and services, the required fare increases would be even higher. The average fare for an average (short) rail trip in southwestern Ontario would increase from $25 to $65. At such fares, the demand for rail travel would likely drop, requiring even higher fares to recover costs.

Pricing all transportation to include charges for environmental damage would, however, modestly improve rail's relative position on some routes. Some rail advocates suggested to us that if the pricing of all modes included charges for environmental damage, passenger rail might be attractive in terms of price. In terms of smog-creating pollution and carbon dioxide ($CO_2$) emissions, rail's performance compared with competing modes is mixed.[3] Transcontinental trains, with their sleeping and dining cars, consume more fuel per passenger-kilometre and create more $CO_2$ and other pollutants than airplanes or cars (Chapter 7).

Rail travel is generally less polluting than travel by air or car if enough trains with modern equipment operate at good occupancy rates over moderate distances — for example, the Toronto–Ottawa–Montreal service. Even with modern trains and good occupancy rates, rail is not less polluting than intercity bus. Compared with all the rail services we examined, and all classes of emissions, intercity bus provides service at a lower environmental cost per passenger-kilometre.

Although rail has not kept pace with the emissions reductions achieved by the car, bus or airplane, we recognize that changes in technology could reduce train emissions. Although the potential for emission reduction in conventional rail is limited in the short term, using improved diesel engines or electric trains could reduce emissions (depending on the source of the electrical power).

The expenditures required for the termination of VIA Rail would cost taxpayers approximately $300 million, or less than one year of subsidy. As a corporation, VIA Rail has obligations and long-term contracts, but also assets that could be sold. In particular, railway labour contracts negotiated during the late 1980s provide long-term guarantees of income to many employees. These contracts, which are similar to contracts with CN and CP, mean that, after eight years of work, many employees are guaranteed their salary until pension age, regardless of whether they work or not, provided they are available for work. Payments that might be required under these contracts are believed to have a present discounted value of $350 million.

Other costs for the orderly termination of VIA Rail would relate to lease- and supplier-contracts, unfunded pension liability, losses in revenue during the last months of train operations, payments for environmental damage and other costs of winding down a company. These costs would be offset by approximately $250 million from the net proceeds of the disposal of assets used in VIA Rail's operations — the sale of cars, locomotives, track, stations, maintenance shops and land.

## RECOMMENDATIONS FOR PASSENGER RAIL

The question of the future of passenger rail service and specifically VIA Rail was one of the most difficult — if not the most difficult — that we faced. Historically, Canada has had an enviable nation-wide passenger rail system that played a major role in the development of the country and was an essential service in times of emergency. And yet, changes in overall demand for passenger transportation during the last 40 years (Chart 2-5) have left passenger rail in a precarious position. Not one of VIA Rail's services, at present cost and revenue levels, approaches recovery of its operating costs, let alone capital costs. Nevertheless, significant numbers of Canadians from coast to coast expressed concern about the future of passenger rail and told us that they wanted the trains to continue running. Some interveners strongly supported both transcontinental and regional services. It is unlikely, however, that the VIA Rail operation, as currently structured, could become self-sufficient under our principles and objectives for future passenger transportation in Canada, even with full allowance for environmental charges.

We believe, however, that there may be a future for passenger rail in Canada, and that it should be given a chance under favourable conditions to prove itself in the same competitive market as all other modes.

We considered recommending a system whereby a number of service providers could bid for subsidies below the levels noted in Table 12-3. This would be in keeping with our "fit, willing and able" principle. There is, however, a risk that a permanent system of subsidies would emerge from this approach, or that VIA Rail would find itself dismantled and replaced in part by a number of even more fragile companies. For these reasons, we prefer a transition policy based on a continuation of VIA Rail as the primary provider of intercity passenger rail transportation.

Therefore, we **recommend** that:

---

**12.1 The federal government pass legislation to give VIA Rail a corporate mandate that allows it to operate on a commercial basis, with such legislation to provide for:**

**(a) a "sunset" provision on the general subsidy that allows 10 years to achieve break-even, after which the subsidy would be withdrawn;**

**(b) a 10-year schedule of declining operating subsidies to VIA Rail so that such subsidies reach zero at the end of the 10-year period;**

**(c) a 10-year budget for VIA Rail for capital projects that have a reasonable chance of repaying the costs in future revenues;**

**(d) sufficient freedom to VIA Rail's management to ensure that it can exploit the advantages of the rail mode to the fullest, including investment, route selection, service levels and pricing, but having due regard for competition policies that prohibit predatory pricing;**

**(e) the ability for VIA Rail to borrow funds in the capital markets, but with no government guarantee, once the government is satisfied that VIA Rail will be viable; and**

**(f) any long-term commitment by VIA Rail, including wind-down costs, to be accounted for and provided for within the 10-year subsidy schedule.**

---

Adherence to this mandate would be monitored by the National Transportation Agency. VIA Rail management would also, of course, be subject to general competition rules prohibiting anti-competitive behaviour. It would be important that competition policy prevent subsidized rail services from using predatory pricing to undercut bus and air services during the transition period.

VIA Rail can notify the federal government that it intends to abandon a route prior to the end of the transition period. In that event, the federal government should reduce the subsidy to reflect this. VIA Rail management should decide whether or not to have a transcontinental train, its frequency, and what route it should take. Other questions, such as the type of service (luxury, tourist, seasonal or year-round), would be handled the same way.

If a government believed that a different route should be served or that there should be greater service frequency, then that government would be required to say so publicly, to contract with VIA Rail for the service, and pay for the service out of their general tax revenues.

We expect that, on routes that it aimed to make viable, VIA Rail would make major efforts to improve service; these could include a reservation system with seat selection, terminals with better accessibility for travellers with disabilities and elderly travellers, and improved speed and in-train amenities to attract business travellers.

Provinces and regions might choose to operate regional or local passenger railways, or to contribute additional monies (through VIA Rail or another rail carrier) to achieve local objectives, such as reduced highway congestion, and improved urban development.

Therefore, we **recommend** that:

---

**12.2 VIA Rail be free to compete for other services, including operating commuter services and transporting mail.**

---

**12.3 VIA Rail be required to file with the federal government and to publish detailed annual operating plans and financial reports that include the costs and revenues related to individual routes.**

**12.4 At the end of 10 years, all routes be unsubsidized and open to any fit, willing and able new entrant.**

## REMOTE SERVICES

As we stated earlier, most of the 6,700 kilometres served by mandatory remote trains are not truly remote. Many of the routes are parallel to highways and are served by bus and air carriers, particularly between many of the larger centres. Since passengers have alternative modes of transportation available, rail ridership on these routes has been decreasing. These services have low cost-recovery rates, none recovering more than 10 percent of their costs (Table 12-5).

All remote services should be limited to bringing passengers to the closest convenient point of transfer to a commercial carrier. With few exceptions, a strictly remote route would not be physically connected to VIA Rail's network. These services would not require VIA Rail's marketing, reservations and customer services and might not need to be provided by VIA Rail. An example of such an alternative is provided for one such route in Chapter 18.

Mixed trains (freight trains with a passenger car, or even a combination passenger-local freight car) may be the cheapest way to provide rail passenger service in some remote areas. For example, mixed trains are used on the weekly Wabowden to Churchill service and on some runs from The Pas to Lynn Lake. Historically, the freight railways, which operate these trains, have not charged for crew, locomotives and track access when such passenger accommodations are added, but only for fuel and maintenance for the passenger cars.

Although mixed trains may provide an inexpensive alternative to passenger-only rail service, the combination of freight and passengers does have problems. While passenger service is usually on a fixed schedule, freight assignments often do not match the passenger schedules or routes. In addition, passenger service requires more stops than freight traffic, causing inefficiencies for shippers. Where mixed train service is appropriate, it may be simpler to have it provided by the freight carrier.

We therefore **recommend** that:

---

**12.5 Where governments judge that a subsidy for passenger transportation to remote communities is justified:**

- **(a) the most efficient mode and carrier be used and, where feasible, a competitive bidding process be implemented;**
- **(b) any subsidized remote access service (regardless of mode) be designed to take passengers out to and bring them in from the closest convenient point where transfer can be made to a commercial unsubsidized carrier; and**
- **(c) subsidies and their purposes be open to public scrutiny.**

---

## HIGH-SPEED RAIL

Governments and industry have been investigating high-speed rail for the Windsor to Quebec City corridor. The feasibility of high-speed rail in this corridor has been the subject of many studies by potential carriers, equipment manufacturers and governments. It has also had a great deal of promotion in the media. Early research on the viability of high-speed rail was inconclusive, prompting the provinces of Ontario and Quebec, in conjunction with the federal government, to initiate another series of studies. These studies are inquiring into the development, installation and operation of a high-speed rail system in the Windsor to Quebec City corridor. They include:

- assessing market feasibility;

- exploring specific technologies;
- identifying corridors, stops and interconnections with other transportation services;
- defining the roles of the private sector and governments in implementing high-speed rail; and
- assessing industrial benefits.

We have neither the expertise, the time, nor the budget to duplicate such studies and, therefore, cannot comment on the technologies available, the estimated costs, projected ridership or revenues of these systems. On the other hand, it is within our mandate and our resources to examine high-speed rail from the perspective of long-term transportation planning and policy.

There are many high-speed rail technologies on the market and more will become available in the future. In addition to the Swedish, Japanese, French and German high-speed, steel-wheel-on-rail technologies, both the Germans and the Japanese are developing magnetic levitation systems (maglev).

High-speed rail systems have high fixed costs and low variable costs. As a result, they need high ridership to be successful. Otherwise, they run large deficits. Successful high-speed rail operations in France and Japan have had ridership levels that have allowed them to charge moderate fares with a range of discounts. Modestly discounted fares create more demand for travel, which, in turn, leads to increased frequency and convenience in scheduling for travellers. This cycle has led to double-digit increases in ridership. The key issue is whether there would be enough riders in any Canadian corridor to pay the costs for a high-speed rail system.

There are already buses, airplanes and cars operating in these corridors, and a subsidized high-speed rail service would have unfair advantage over these private-sector services, and cause inefficiencies in the transportation system. In addition, with our recommendations concerning VIA Rail in place, some of VIA Rail's Windsor to Quebec City corridor services might become commercially viable. We believe that a high-speed rail system should be treated consistently with our principles. Any high-speed rail system, like any transportation system project, should be paid for by transportation system users who would benefit and not by the taxpayer. In particular, as we said in our Interim Report:

> From the point of view of an integrated transportation system, it is important that further studies give due account to spill-over benefits such as relief of congestion and reduction of accidents. Since there are joint costs and benefits in an integrated system, it is also important to assign each mode its correct costs. For example, some of the cost of building rail underpasses and overpasses should be assigned to highways, since highway users also benefit from the availability of this infrastructure, and since joint costs of intersections can be assigned to a single mode only if the other mode sharing the intersections has been given "right of way."

Therefore, we **recommend** that:

**12.6 Governments invest in high-speed rail infrastructure only when the expected transportation system benefits exceed the costs, and taxpayers do not have to pay any operating subsidy.**

**12.7 The benefits and costs of any high-speed rail project in which a government invests or subsidizes be made public and the public be consulted on the implications of the government's decision.**

**12.8 The federal government establish the regulations under which any high-speed rail system would operate, including safety and environmental regulations.**

In this chapter we have discussed how our principles can be applied to improve the passenger rail sector, a mode of transportation that is presently heavily subsidized.

# ENDNOTES

1. Some of VIA Rail's documents pool the results for all operations between Windsor and Quebec City.

2. A Rail Passenger Action Force (H.M. Horner, R. Fortin and N. Vincent) was appointed in November 1984 to report by May 1985. The Action Force's objective was a new national rail passenger plan.

3. This discussion is based on current VIA Rail technology. We discuss elsewhere the possible benefits from alternatives, such as high-speed electric railway technologies.

# CHAPTER 13

# APPLYING THE PRINCIPLES TO INTERCITY BUS CARRIERS

## INTRODUCTION

In examining the intercity bus carrier industry, we asked:

- What is the role of the bus in delivering economical transportation to Canadians?
- Would this role be more effectively performed if the industry were more open to new entrants?
- Would the intercity bus industry remain viable and competitive if economic regulation was substantially relaxed?
- Would a less-regulated bus industry still deliver transportation service to Canada's rural communities?

## THE BUS INDUSTRY IN CANADA

### MARKETS

Most bus travellers use this service because it is the cheapest form of intercity travel, particularly for those who do not have a car or who are unable to drive. Thus, those who use the bus most heavily are people of modest means, such as students and some older people. Most bus travel is for recreation or visits to family and friends, although there is some business travel on short-haul routes.

Some bus companies have had limited success in offering luxury services (with spacious seats, refreshments and other amenities) at higher fares than for conventional services. In general, however, premium bus services have failed to attract sufficient riders to render them viable.

Buses serve many Canadian communities. According to the *Official Canadian Bus Guide*, in 1991, the intercity bus industry provided scheduled service to approximately 3,000 points in all provinces and territories (down from 3,400 in 1978).[1] Most travellers use the bus for short trips. In 1991, bus passengers travelled an average distance of less than 200 kilometres.

Bus operations are diverse, from large operators with multiprovincial service to small carriers offering only local services. Greyhound Lines of Canada Ltd., the largest bus operator, has 400 buses serving an extensive route system stretching from Vancouver to southwestern Ontario, and north into the Yukon and Northwest Territories. Dewdney Trails operates a service three times a day each way between Castlegar and Trail, British Columbia, a 30-minute trip. An even smaller operation, Atlin Coach Lines, provides a combined freight and passenger service for six to eleven passengers daily from Whitehorse, Yukon Territory, to Atlin, British Columbia.

## REGULATORY ENVIRONMENT

Economic regulation of the scheduled intercity bus industry in Canada, in particular the restriction of entry by firms that would compete with existing services, continues today. This contrasts sharply with other countries that have opened the scheduled intercity bus industry to greater competition (notably the United Kingdom and the United States), and with the relaxed economic regulation of the air transportation and freight transportation industries in Canada. Bus regulation is enforced by provincial/territorial transport boards, which have authority over carriers whose operations are entirely within a single province or territory. In addition, the federal government has delegated its authority to the boards for carriers whose operations extend beyond the province or territory.

## COSTS AND REVENUES

Of all the types of passenger transportation, bus travel comes closest to paying its way. As we noted in Chapter 3, intercity buses pay fuel taxes that approximately cover the costs of their use of the roads, and would remain the most inexpensive type of public transportation if travellers paid the full costs of bus transportation, including charges for environmental damage and the costs of safety and accidents.

Many bus carriers also provide freight (parcel) services. In rural areas, the bus is often the only carrier of parcels that are over the Canada Post weight limit, and courier companies often use the bus service to deliver their packages. These freight services are an important source of revenue for bus carriers in remote and rural areas, but are much less significant to carriers in the more densely populated southern Ontario to western Quebec region, where a variety of courier, messenger and package delivery services compete for this business.

Charter services are also a source of revenue for the bus industry. In the more populous regions of Canada, most small, scheduled bus carriers and a significant number of the mid-size carriers earn most of their revenues from charter business, and to a lesser extent from school-bus contracts. For Greyhound, Voyageur Colonial and other large carriers, charter service is a profitable use of idle bus capacity.

## TRENDS

The bus industry is an important participant in intermodal passenger transportation. Buses provide a public link to and between other modes of transportation. For example, bus and van services connect communities, train stations and airport terminals.

The market share for intercity scheduled bus service has been declining steadily. Since the 1950s, bus ridership has been dropping while total intercity passenger travel has grown. The intercity bus has been steadily losing ground to the car for short-distance travel and to the airplane for long-distance trips. The bus must also compete with subsidized rail service, especially in the Toronto–Ottawa–

Montreal triangle and in southern Ontario. The bus industry has responded to declining ridership by cutting back service frequency and route-kilometres and by raising fares.

The bus industry is highly concentrated and regionalized. In 1987, the five largest carriers held nearly 90 percent of the value of the assets in the industry, earned 84 percent of the revenues, and carried 81 percent of the passengers — up from 66 percent in 1980.

In eastern Canada, most carriers exchange passengers at or near their provincial borders. To get from Hamilton to Halifax, a person must travel using five different carriers, changing buses each time. Only Greyhound provides significant multiprovincial service — from Vancouver to Toronto.

Buses do not pollute the environment as much as other types of passenger transportation do. Buses consume less fuel per passenger-kilometre, resulting in lower carbon dioxide emissions. Current diesel-engine buses do have significant smog-inducing emissions, but there is considerable potential for improvement.

## WHAT CANADIANS TOLD US

### THE PUBLIC

In our public hearings, Canadians had little to tell us about bus transportation. In our review of Canadians' travel preferences, we found that they view buses as uncomfortable, and particularly poor in seating space and ventilation. They also complain about the condition of some bus terminals.

### THE INDUSTRY

The strongest views on bus travel that we received came from the bus companies and their representatives, who made two major points:

The first point was that they suffer from unfair competition from VIA Rail (especially in the Toronto–Ottawa–Montreal triangle), because VIA Rail is highly subsidized by taxpayers. VIA Rail has been aggressive in its pursuit of market share in the shorter-distance, but higher-density markets. While its campaign has aimed in part at the air mode by emphasizing faster, more convenient and better service, VIA Rail also competes with the bus carriers through special discount fares. The bus industry believes that subsidized passenger rail service limits its ability to offer more and better services to bus customers. VIA Rail, on the other hand, argues that it pays for the infrastructure (stations and track) it uses, while buses do not pay for use of the roads.

The second major point was that the bus industry endorses the present regulatory regime, which restricts competition and allows profits to be generated on high-volume routes, but requires carriers to continue service on low-volume, unprofitable routes. The bus carriers argue that this system, with its cross subsidization, is necessary, if they are to provide service to smaller communities.

## GOVERNMENT POLICIES: PAST AND PRESENT

### REGULATION

Regulation of the intercity passenger bus industry in Canada was introduced by provincial governments in the early 1930s to stabilize the industry. In 1954, in response to a complaint by a bus company, the Supreme Court of Canada determined that the federal government was responsible for every bus and truck operation whose business was extra-provincial — that is, extending beyond a single province or territory.

Because the federal government had no legislation, administrative structure or expertise in place, Parliament enacted the *Motor Vehicle Transport Act* of 1954. This Act delegated federal responsibility for the economic regulation of motor-vehicle transport, including bus transport, to the provinces.

The *Motor Vehicle Transport Act, 1987* substantially deregulated trucking, but bus regulation was essentially unchanged. Provincial transport boards are to issue licences and regulate tariffs and tolls for extra-provincial bus operations ". . . on the like terms and conditions and in the like manner as if the extra-provincial bus undertaking were a local bus undertaking. . . ."[2]

Although all provinces and territories regulate bus carriers, there are differences in their manner of doing so. Eight of the provinces grant a bus company authority to operate a scheduled intercity service only if the applicant is able to prove public convenience and necessity. A public hearing is held if there are any objections to the proposed service. New Brunswick and Prince Edward Island removed this requirement in 1987, and now have a reverse onus test — an application is denied only if it is proven that the application would be detrimental to the public interest. In every province and territory, changing or abandoning a service requires approval by the provincial/territorial regulator.

Also in every province and territory, bus companies must file fares and obtain approval for them from the provincial/territorial regulatory authority. In Alberta, Saskatchewan, Manitoba and Newfoundland, only maximum fare levels require approval. All provinces and territories allow for public hearings to handle objections to fare increases. At the time of writing this report, the Maritime provinces were engaged in discussions that may lead to a common regulatory regime for intercity bus operations in New Brunswick, Nova Scotia and Prince Edward Island. It is expected that any common regime would be at least as open to competitive services as the relatively liberal regulation in New Brunswick and Prince Edward Island.

Charter services require separate licences in seven provinces. The reverse onus test applies to charter services in Alberta, New Brunswick and Prince Edward Island.

A number of scheduled bus services link Canadian and U.S. centres. These services are regulated by the provinces under the delegation of federal responsibility for extra-provincial carriers. They are also subject to U.S. regulation. U.S. federal regulation, which applies to interstate and international services, and the regimes of several of the states, less strictly control introduction of new services, changes in service, and pricing, than Canadian regulation.

### COMPETITION

Competition among bus carriers on the same routes is generally discouraged. While there are a few exceptions, the bus industry consists mostly of regulated intercity monopolies. Even overlapping routes, such as Greyhound's trans-Canada service and the provincial services of the Saskatchewan Transportation Company, do not usually compete for the same passengers.

## THE EFFECTS OF REGULATION

### CROSS SUBSIDIES

Cross subsidies help maintain service on low-volume routes. Regulation of fares and routes allows carriers to earn high returns on high-volume routes in exchange for an explicit or implicit commitment to provide service, below cost if necessary, on other routes. Our analysis, based on average costs and revenues for various route types, suggests that:

- The most lucrative express routes could make a profit equal to half of the average fully allocated costs including return on investment.
- Mixed services (where intercity passengers are carried, but stops are also made at small communities) and long-distance services are generally profitable.
- Some local routes that parallel express service between major urban centres recover less than 25 percent of their costs.

### OTHER EFFECTS

Regulation has its drawbacks. Our analysis suggests that average intercity bus transportation costs are higher than they would be in a more open market, in part because of lower efficiency. As discussed earlier, the bus industry has been losing market share, and is highly concentrated and regionalized. A policy that provides greater room and stimulus for a more entrepreneurial approach offers the possibility of improving bus service where it has the greatest potential.

## THE CASE FOR A COMPETITIVE BUS INDUSTRY

Would opening the bus industry to competition result in a healthier industry, lower fares and improved services for travellers?

The experience in the United States and the United Kingdom offers useful insights. The United States and United Kingdom started regulating their intercity bus industries more than 50 years ago, in 1935 and 1930, respectively, and substantially deregulated them half a century later within a span of 22 months.

### THE U.S. EXPERIENCE

In 1982, the U.S. Congress substantially, but not totally, deregulated intercity bus services. Some states have followed suit.

The major carriers have experienced financial difficulty and reorganization. The general economic malaise in the U.S. intercity bus industry was evident before 1982. The cost reduction achieved through franchising, renegotiating wage contracts, changing work rules, and eliminating unprofitable routes (which was possible because of regulatory reform) was not enough to stop the downward trend.

A major development after regulatory reform in the United States was the Greyhound-Trailways merger. Greyhound in the United States (which does not have a corporate relationship with Greyhound in Canada) now controls 85 percent of the revenues generated by the major interstate bus companies. It provides the only public intercity transportation in 9,000 of the approximately 9,500 markets it serves.

The Greyhound-Trailways merger has resulted in service to rural communities that operates like the airlines' hub-and-spoke system. Small carriers affiliated with Greyhound use vans to provide service in areas where demand is insufficient to warrant using full-size buses. These so-called "feeder lines," which are linked to communities served directly by Greyhound, are operated by independent entrepreneurs who act as agents for Greyhound and receive a portion of the fare.

There is no question that there has been reduction in the availability of intercity bus service to small communities by the major bus companies; but much of this would have occurred in any event. Bus ridership, routes and service points were decreasing prior to regulatory reform.

## THE U.K. EXPERIENCE

In the United Kingdom, regulatory reform was more extensive than in the United States. British intercity bus travellers have benefited, on average, from lower fares and improvements in the quality of service.

One of the effects of deregulation was reorganization and concentration within the express-bus sector. Six major private companies combined to compete with the publicly owned National Express, but failed. Within four years of regulatory reform, National Express, which was privatized in 1987, had become, once more, a monopoly supplier on many routes where private operators had initially offered new service. While National Express has recaptured the market on most routes, the threat of new companies entering the market appears to have kept fares from rising.

As in the United States, there was some reduction in lower-volume bus services after regulatory reform. Discontinuing intercity services, however, appears to have denied few people access to adequate intercity transportation.[3] Local authorities have provided subsidies to prevent loss of the services that link rural areas and small communities to larger urban centres. These services have, in general, been operated by private-sector bus companies and have achieved cost reductions.

## COMPETITION AND LOWER FARES

Our research indicates that there would be advantages to travellers if the Canadian bus industry faced more competition. In a more open market, carriers would rationalize services and trim costs or lose market share on profitable routes to lower-cost competitors. Easier market entry would invite innovative services that could reverse, or at least slow down, the current decline in bus ridership.

Competition or potential competition on higher-volume routes should lead to lower fares. Because carriers would be deprived of exclusive rights, fares for express services, even between cities of moderate size, should fall. International experience supports this conclusion, as do the results for one of the few routes in Canada where competition exists. Greyhound currently competes in Alberta with Red Arrow's luxury service between Calgary and Edmonton and between Edmonton and Fort McMurray. Fares on these routes are lower than on similar routes.

On short low-volume routes where fares currently fall well below costs, and where competition is unlikely, fares would be expected to rise after removal of regulation. This would contribute to keeping some of the routes viable.

## INNOVATION

Relaxed economic regulation would encourage innovation and entry of new operators into some markets, and more carriers in a market should increase service choice. Intermodal connections and innovative management techniques would be encouraged by a more competitive environment. Mini-bus operations and a variety of part-time ventures offering scheduled service would replace inefficient full-sized coach services to some smaller communities.

Large carriers would not necessarily force smaller operators out of business. Our studies indicate that large carriers do not always have the lowest operating costs. In fact, the costs per unit of service of some of the small and medium-sized carriers were among the lowest of those we studied. Some small carriers operate profitable rural services in markets that larger regional carriers have chosen not to serve.

Therefore, we **recommend** that:

---

**13.1 The *Motor Vehicle Transport Act, 1987* and relevant provincial and territorial legislation be amended to substantially relax the economic regulation of buses to:**

- **(a) reduce the restrictions for entry to "fit, willing and able" criteria;**
- **(b) require that route abandonments be subject only to adequate public notice;**
- **(c) require only the publication of schedules and fares; and**
- **(d) ensure that carriers be subject to the *Competition Act*.**

---

Our recommendation is addressed both to the federal government, regarding extra-provincial bus carriers, and to provincial/territorial governments, regarding remaining carriers. We note that extra-provincial carriers currently account for a large share of total passengers carried, and that other carriers could opt for extra-provincial status by extending their operations beyond a single province or territory. Thus, federal action would have the effect of deregulating most of the industry. To implement the recommendation, the federal government could withdraw its delegation of powers to the provinces/territories, or it could negotiate new agreements whereby provincial/territorial regulatory boards continue to enforce a modified motor vehicle transportation act with which we hope provincial/territorial regulatory regimes would be in harmony. We prefer the solution that creates the simplest administrative procedures for the carriers.

## COMPETITION LEGISLATION AND ENFORCEMENT

The success of relaxing economic regulation of intercity busing will depend on competition developing in the present regional monopoly markets. Such competition may come from large bus operators expanding into each other's traditional markets. We expect that charter carriers and small local operators that presently connect with the large monopoly carriers may also prove to be significant long-term competitors.

Potential competitors must be confident that federal competition legislation will ensure them a fair opportunity to compete and protect them from monopoly practices. The present *Competition Act* is a substantial advance over its predecessor, but the federal government should assure itself that the Act provides sufficient response and redress procedures to encourage active and effective competition in a newly deregulated bus industry.

We understand that protection for the small carriers that extend operations into the routes and terminals dominated by larger carriers would fall within the "abuse of dominant position" and the "refusal to deal" provisions of the Act.

We recognize also that competition policy applies to other sectors of the economy as well as transportation, and that the federal government must consider a range of factors, including jurisdiction, that we are unable to assess. Nevertheless, if Canadian travellers are to gain the full benefits of relaxed economic regulation, potential entrants into transportation markets must not be discouraged by fears of monopoly practices on the part of well-established carriers.

Therefore, we **recommend** that:

**13.2 The federal government review the *Competition Act* and related policy and, if required, strengthen the powers needed to prevent anti-competitive practices in the intercity bus industry.**

## SERVICE TO SMALL COMMUNITIES: THE TRANSITION

We are concerned about the impact of regulatory reform on services to small, rural communities. Some communities will enjoy reduced prices and better service because bus companies will use more suitable equipment for the market and reduce their costs. In less populated regions, smaller and older buses and part-time operators with mini-vans will enter the bus business, as is common in Newfoundland.

Fares for shorter rural trips could rise with reduced regulation. Some rural routes would survive, but with reduced frequency. Some communities would no longer be served by major carriers with full-size coaches. Others could lose scheduled service if there is very low demand for bus travel.

We believe that, after a period of adjustment, small communities that provide a regular travel market will be served. Experience and our studies indicate that bus operations can be viable in quite small markets. Regulatory reform frees the market and allows each carrier to choose to operate any route or type of service based on its commercial interests. The result is that services appropriate to the size of the market emerge.

We believe that bus travellers on profitable routes should not have to subsidize travellers on unprofitable routes. Bus riders on profitable rural and intercity routes are often those who cannot afford any other mode of travel. These bus riders should not pay extra to provide transportation on unprofitable routes.

We recognize that transition provisions may be required so that bus service in some areas is not lost while the industry adjusts.

Therefore, we **recommend** that:

---

**13.3 If necessary to avoid steep increases in bus fares on particular routes following the relaxation of economic regulation of the intercity bus industry, transition subsidies be provided on a declining basis not to exceed 10 years and then terminated, with such subsidies being provided on a competitive tender basis to the carrier that can provide a safe service at the lowest cost, and being paid for by taxpayers in those jurisdictions that wish to maintain the service.**

---

In recommending reduced regulation of market entry and exit, we considered a gradual transition to an open market that would allow carriers time to reorganize and reduce costs.

We have decided, however, not to recommend such a transition period. Our reasons are as follows:

- The legislative amendment process will take a substantial period of time, and there will be additional delays before the new provisions come into force.
- One change is sufficient. Carriers and travellers should not have to adapt to a transition regime, only to change again when the transition period is over.
- Some parties may be tempted to manipulate a transition regime to position themselves for a competitive advantage later. A transition period could foster anti-competitive practices.

The bus is the lowest cost way of transporting Canadians to where they want to go. With deregulation of the intercity passenger bus industry, bus travel would become more efficient and even less costly.

# ENDNOTES

1. Russell's Guides, Inc., *Official Canadian Bus Guide,* May–June 1991.

2. The *Motor Vehicle Transport Act, 1987* provides authority for the federal government to exempt a bus carrier from falling under provincial jurisdiction. Such exemption means that the carrier is regulated under the provisions of Part IV of the *National Transportation Act, 1987* and falls under the jurisdiction of the National Transportation Agency. (The corresponding provision in the earlier Act was invoked only once, as a consequence of a dispute between CN Roadcruiser and the Board of Commissioners of Public Utilities of Newfoundland. The Board had restricted the tariff of the federally owned replacement for Newfoundland's passenger rail service.)

# CHAPTER 14

# APPLYING THE PRINCIPLES TO FERRIES

## INTRODUCTION

Canada has the longest coastline of any country in the world and has major island groupings in temperate climatic zones — including three on which provincial capitals are located. Inland, the St. Lawrence River and the Great Lakes are two of the country's and the world's major waterways. In the past, when it was easier to travel by water than overland, towns developed along Canada's waterways. Today, water transportation continues to be an important mode of travel for many Canadians.

Ferries provide a variety of passenger transportation services to many Canadians. The operators providing these services range from small to large; some are privately owned and some are publicly owned. For example, the British Columbia Ferry Corporation (BC Ferries), with 38 ships and 24 routes serving 43 terminals, is one of the world's largest ferry services.[1] In contrast, river-crossing ferry services for short distances between two points are provided in many locations by small operations. The variations in ferry services across Canada are as great as the variations in Canada's geography and population distribution.

Taxpayers provide substantial support to ferry services. Measured in costs per passenger-kilometre, ferries are the second most heavily subsidized means of passenger transportation, after rail. Since Confederation 125 years ago, federal and provincial taxpayers in Canada have spent large amounts of money on ferry services. The reasons for these expenditures include meeting constitutional obligations (for example, the provision of ferry service to British Columbia, Prince Edward Island and Newfoundland) and encouraging social or economic development, particularly in Atlantic Canada.

The major intercity ferry operations in Canada are found on the west and east coasts. Most of the ferry routes on the west coast are operated by BC Ferries, a provincial Crown corporation. Marine Atlantic Inc., a federal Crown corporation, provides the majority of the ferry services on the east coast. Other larger ferry services include: the seasonal service between Prince Edward Island and Nova Scotia, operated by the privately owned Northumberland Ferries Ltd.; the St. Lawrence River ferries, operated by the Quebec government; and the Great Lakes service, operated by the Ontario government.

Passenger volume on these ferries varies a great deal. In 1990, BC Ferries carried nearly 20 million passengers,[2] Marine Atlantic carried almost 2.5 million, and Northumberland Ferries approximately 530,000.[3] The next two largest services are: the Matane to Godbout to Baie-Comeau route of the Société des traversiers du Québec, which carried approximately 270,000 passengers in 1990;[4] and the Ontario Northland Transportation Commission's Tobermory to South Baymouth service, which carried over 200,000 passengers in the same year.[5]

Overall, the use of ferry services in Canada has increased in recent years. Most of the increase has occurred on the west coast, where BC Ferries carried a total of 18 million passengers in 1986 and 20 million in 1990. On the east coast, Marine Atlantic's total ridership grew slightly, from 2.3 million passengers in 1986 to 2.5 million in 1990.[6]

There are many different types of ferry services. The following are a few examples:

- The MV *Joey and Clara Smallwood,* a large ferry equipped with a modern navigation system, travels 519 kilometres between North Sydney, Nova Scotia, and Argentia, Newfoundland, twice a week. In 1991, this ferry carried about 15,000 vehicles and 41,000 passengers during its late-June to early-September operating season.

- A high-speed passenger-only ferry service (catamarans travelling at speeds of up to 37 knots) operates in the Georgia Strait between downtown Victoria and downtown Vancouver. The vessels used on this new service can carry up to 312 passengers.
- A privately owned and operated ferry service crosses the Ottawa River between Cumberland, Ontario, and Masson, Quebec, a distance of less than a kilometre. The ferries in this service can carry 13 cars, operate 24 hours a day year-round, with at least 2 ferries in the winter and up to 5 in the summer, and offer 5-minute service during the day and 10-minute service at night.

Many of the shorter ferry services could be described as intercity. These include such routes as Cumberland to Masson as well as the Quebec City to Lévis and Halifax to Dartmouth routes. As well, there are services on both coasts that connect small, remote communities, most of which are completely dependent on these ferries for both freight and passenger service. For the purposes of this report, however, we have focussed on longer intercity trips that are more comparable with intercity trips in other modes.

## WHAT CANADIANS TOLD US

Interveners from the Atlantic region told us that their ferry operations provide essential passenger and cargo services. They argued for increased federal presence and funding to establish more year-round ferry services in the Atlantic provinces. They pointed out that ferry service is an important tool for economic development, both in the role it plays in the tourism industry and as a means of moving freight.

Several interveners urged us to consider ferry service as an integral part of the transportation system in the Atlantic region, rather than as a method for point-to-point travel. They said that ferry services are an extension of the highway and railway systems and recommended further integration of the various modes to enhance the ferry services.

Interveners from British Columbia also told us how important ferry services are to them. They pointed to the role that ferry services could play in a rapid-transit system connecting Victoria and Vancouver. They suggested these cities build rapid-transit systems that link with ferry docks to provide an inexpensive and environmentally safe method of moving large numbers of people (presumably without their cars). Some also suggested establishing local bus service to the ferry terminals because such services would have lower fares than those now charged for special bus service to the terminals.

Interveners emphasized the importance of ferries to tourism and asked for increased service between points in Canada and the United States. Some stressed that ferries should continue to serve remote communities even though such services require subsidies. Several interveners called for an increase in federal funding for British Columbia's ferry services to match that received by eastern Canada. In British Columbia, as in the Atlantic provinces, some suggested that ferry services should be considered as an extension of the highway system.

## CONSTITUTIONAL OBLIGATIONS

Some ferry services are part of early constitutional arrangements. Each of the Terms of Union signed between Canada and British Columbia, Prince Edward Island and Newfoundland included an obligation on the part of the federal government to provide a ferry link to the mainland.[7] In a few cases, the federal government has also agreed to subsidize alternative ferry routes to those set out in the Terms of Union, although no federal constitutional obligation exists for these. The alternative services include the seasonal service between Caribou, Nova Scotia, and Wood Islands, Prince Edward Island, operated by Northumberland Ferries Limited.

Courts and governments have reviewed constitutional obligations for modern transportation. When the federal and provincial governments negotiated these Terms of Union, ferry services played a different role in the lives of Canadians than they do today. Steamships provided ferry services, carried mail as well as passengers, and linked communities in a time of few roads and no air service. Over the years, the function and technology of ferry services have changed considerably. Today, ferries use many different technologies, and passengers can often choose other modes of transportation for many ferry routes. As a result, courts and governments have attempted to interpret constitutional agreements in a modern context.

## BRITISH COLUMBIA

The original federal-provincial agreement was intended primarily to ensure mail service. Under Term 4 of the 1871 *British Columbia Terms of Union*, Canada undertook to "provide an efficient mail service, fortnightly, by steam communication between Victoria and San Francisco, and twice a week between Victoria and Olympia [the capital of neighbouring Washington state]; the vessels to be adapted for the conveyance of freight and passengers." To fulfil its obligations, the federal government subsidized a private steamship operator under a contractual arrangement.

In 1925, the federal and provincial governments agreed that the service between Victoria and San Francisco no longer required a subsidy, and that the British Columbia government should use the subsidy to improve mail service within the province.

In 1977, the federal and British Columbia governments entered into a new arrangement for ferry subsidies.[8] The federal government agreed to pay a block grant of $8 million per year to the province to support ferry service. With annual adjustments to cover inflation, the estimated payment in 1992-93 is $19.9 million.[9] In return for the payment of this subsidy, Canada was "relieved of any and all obligations for the provision of subsidy or other financial assistance over and above the subsidy provided for in this Agreement."[10]

The province is responsible for how the federal grant is allocated and has agreed to "assure reasonable and adequate service and appropriate supervision thereof" in British Columbia coastal waters.[11] The province is also obliged under the agreement to "place appropriate passenger vessels in service . . . to give effective links where required on the coast between communities and principal water and air services."[12]

While the current agreement satisfies the requirements of the Terms of Union, the constitutional obligation to provide the service remains that of the federal government rather than the province.

## PRINCE EDWARD ISLAND AND NEWFOUNDLAND

The federal agreements with Prince Edward Island and Newfoundland ensured specific ferry routes. In 1873, Prince Edward Island joined Confederation with the assurance that the Dominion government would "assume and defray all charges" relating to a list of services, including what has become the ferry service connecting Prince Edward Island and New Brunswick.[13]

Term 32(1) of the 1949 *Newfoundland Act* provided that "Canada will maintain in accordance with the traffic offering a freight and passenger steamship service between North Sydney and Port aux Basques, which, on completion of a motor highway between Corner Brook and Port aux Basques, will include suitable provision for the carriage of motor vehicles."[14]

Marine Atlantic operates the two ferry services that fulfil Canada's constitutional obligations to these provinces. One service operates between Cape Tormentine, New Brunswick, and Borden, Prince Edward Island; the other, between North Sydney, Nova Scotia, and Port aux Basques, Newfoundland. Terms 32(2) and 32(3) of the *Newfoundland Act* limit the rates that can be charged for traffic to Newfoundland.[15] This is the only rate limitation for any constitutionally required ferry service.

The possibility of fulfilling the constitutional ferry obligation to Prince Edward Island by replacing the ferry service operated by Marine

Atlantic with a fixed link has been under consideration for several years. In the spring of 1992, in response to a federal government invitation, three developers submitted proposals to construct and operate for 35 years a fixed link between New Brunswick and Prince Edward Island. At the time of writing, all of these bids had been rejected as not complying with the federal government's requirements, and discussions were ongoing. The invitation for proposals provided that at the end of the 35-year period, the structure would become the property of the federal government and would be operated as an interprovincial bridge. During the intervening period, the federal government would pay the operator a predetermined amount that would be similar to the amount that the ferry subsidy at existing levels would have been, plus other avoidable costs of the service. Had our principles been adopted, however, the ferry subsidy would have been substantially lower and the proposed fixed link would only meet our investment criteria with a higher bridge toll.

## MARINE ATLANTIC AND BC FERRIES — COSTS AND REVENUES

The two largest ferry companies in Canada receive different levels of government subsidies.[16]

Marine Atlantic Inc.'s revenues totalled nearly $218 million in 1990. Of this amount, $147 million[17] came from federal taxpayers and the rest, $71 million, came from ferry passengers and freight.

The commercial portion ($71 million) of the total revenues came from fares and charges for other on-ship services, such as restaurants, and vessel and miscellaneous services. Charges for the direct movement of passengers and vehicles accounted for almost 78 percent of commercial earnings.

Of the federal payment ($147 million), $96 million was for direct operating expenses (excluding any allocations for administrative or capital costs). Approximately 60 percent of this latter amount was for the two constitutionally required services ($22.7 million for the Prince Edward Island service and $36 million for the Newfoundland service).

BC Ferries' revenues totalled $242 million in 1990. Of this amount, $229 million came from commercial revenues, including tolls for passengers and vehicles, and catering and other income, and $13 million came from British Columbia taxpayers as an operating subsidy.[18] Passenger-transportation-related revenues accounted for almost 81 percent of commercial revenues.

In addition to operating revenues, various forms of capital assistance are provided by federal taxpayers to Marine Atlantic and by British Columbia taxpayers to BC Ferries.

There are large differences in average costs for the two ferry companies. Average passenger costs for Marine Atlantic are approximately double those of BC Ferries. Average passenger costs, however, for BC Ferries' services, excluding the services between Vancouver Island and the mainland, are similar to those for Marine Atlantic's operations. Some of the reasons for the large differences in average costs are as follows:

- BC Ferries has a more even distribution of annual traffic than does Marine Atlantic. Peak season activity represents about 40 percent of total annual passenger traffic for Marine Atlantic, but only about 22 percent for BC Ferries.[19] Marine Atlantic vessels are constructed to handle this peak season traffic and therefore have unused capacity in the off-season. In contrast, more even year-round operation allows BC Ferries to make fuller use of its vessels.
- Marine Atlantic has higher costs because its vessels must be ice-strengthened for winter conditions. Ice strengthening increases initial capital costs and, as a result of the added vessel weight, operating costs increase as well. BC Ferries, however, operates primarily in the southern part of the province, where weather conditions are less severe. This results in fewer capital-intensive shore facilities, lower vessel operating expenses and fewer cancellations because of bad weather.

- Wage rates do not contribute to Marine Atlantic's higher operating costs. Labour costs are 44 percent of Marine Atlantic's total operating costs, and 55 percent of BC Ferries'. In addition, BC Ferries' wages are, on average, 11 percent higher than those of Marine Atlantic. Administrative costs do not differ substantially between the two operators — they represent 11.6 percent of Marine Atlantic's total costs, and 14.3 percent of BC Ferries'.

## THE PRICING OF FERRY SERVICES

In Chapter 4, we recommended that travellers pay the full costs of the transportation services they use and that carriers pay the full cost of the terminals, links and traffic control services they use. Thus, passengers (and freight shippers) should pay the full costs of the ferry services that they use, and operators of ferry services should charge travellers the full costs of providing their service, including the costs of the provision of terminals, harbour fixtures and navigational aids.

Any additional costs imposed on ferry operators because of government requirements (such as requirements to purchase local or Canadian manufactured goods or equipment or to have maintenance or refitting of vessels carried out at specific locations) should be clearly identified. These costs should be funded by the government concerned, out of the appropriate industrial or regional development budget, and should not be included as part of the costs to be recovered through fares.

In addition, in Chapter 4 we recommended that terminals, links and traffic control services be individually priced on a terminal-by-terminal, link-by-link and service-by-service basis. The nature of a ferry service allows each service or link to be priced individually.

We realize that the goal of full payment of costs cannot be achieved immediately, but, from this point on, governments should use this goal when setting policy, making transportation investments, and looking at future programs and projects. Avoidance or minimization of subsidies on existing services results in a more favourable environment for introducing innovative services. The new high-speed ferry service introduced early this year between Victoria and Vancouver is an example of what can happen in a free market. It competes with a BC Ferries' service that receives little or no subsidy.

We recognize that, for some routes, ferry rates would have to increase considerably (more than 10 percent annually) to achieve financial self-sufficiency within the next 10 years. In other cases, ferry rates are already at, or near, cost-recovery levels.

Table 14-1 compares the rates charged on routes of similar length for Marine Atlantic and BC Ferries. The figures show that:

- Marine Atlantic's one-way fare per kilometre for the shortest route shown is higher than for a similar length route operated by BC Ferries;
- one-way fares per kilometre on the longest routes differ substantially on the east and west coasts; and
- fares on medium-length routes also vary. On the east coast, the Yarmouth to Bar Harbor route is almost the same length as the North Sydney to Port aux Basques route, but its one-way fare per kilometre for a passenger is nearly three times as much in the peak operating season. The fare differential is less in the case of the one-way fare for a car and driver. Both routes are operated by Marine Atlantic. BC Ferries' fare for a comparable-length service from Prince Rupert to Skidegate is similar to that for Marine Atlantic's North Sydney to Port aux Basques route for a passenger, but nearly one-third more for a car and driver.

In the transition to ferry services where travellers pay the full costs of the services they use, ferry operators will have to raise rates and/or reduce costs on most routes. We realize that such adjustments will take time.

*Table 14-1*

*SELECTED FERRY RATE COMPARISONS, MARINE ATLANTIC (M.A.) AND BC FERRIES (B.C.), 1992*

| Service | Crossing distance (km) | One-way fare auto and driver ($) | Fare/km auto and driver ($) | One-way fare passenger ($) | Fare/km passenger ($) |
|---|---|---|---|---|---|
| Cape Tormentine to Borden (M.A.) | 15 | 11.75 | 0.78 | 3.25 | 0.22 |
| Horseshoe Bay to Langdale (B.C.) | 18 | 12.75 | 0.71 | 2.75 | 0.15 |
| North Sydney to Port aux Basques (M.A.) | 178 | 66.00 | 0.37 | 16.00 | 0.09 |
| Yarmouth to Bar Harbor (M.A.) | 185 | 120.00[a] | 0.65 | 45.00[a] | 0.24 |
| Skidegate to Prince Rupert (B.C.) | 172 | 82.00 | 0.48 | 17.00 | 0.10 |
| North Sydney to Argentia (M.A.) | 519 | 145.00 | 0.28 | 45.00 | 0.09 |
| Bear Cove to Bella Bella to Prince Rupert (B.C.) | 507 | 260.00[a] | 0.51 | 85.00[a] | 0.17 |

**Sources:** BC Ferries and Marine Atlantic Inc.

**a.** Peak-season rate.

**Note:** Peak-season fares shown where applicable.

Therefore, we **recommend** that:

---

**14.1 Governments, in eliminating the capital and operating subsidies on individual ferry routes (including, where possible, the routes provided under the Constitution), establish transitional periods not to exceed 10 years in those cases where moving to immediate cost recovery would result in steep annual fare increases.**

---

We also recognize the constitutional obligation of the federal government to ensure that adequate service continues to Prince Edward Island and to Port aux Basques, Newfoundland, and the constitutional limit on rates for the Newfoundland service. Wherever such routes require subsidies to cover costs, we believe that governments should ask the following:

- Are the fares appropriate?
- Is the operation furnishing services of sufficient benefit to justify continuation in its current form?
- Are there adequate pressures to achieve cost savings?

It may be possible, with increases in rates and cost reduction, that a constitutional service can be financially viable. Under those circumstances we think that is what should happen. We also recognize that, even with the most cost-effective service, and with rates that maximize revenues (subject to any constitutional fare constraint), traffic volumes may be such that a deficit might still be the case and, given the constitutional obligation, the federal government would have to continue to meet it.

In reviewing the options for moving toward elimination of the subsidy, the federal government should consider whether contracting out the provision of service, with fares ultimately to be set by the operator but with the transitional subsidy, would be cost effective. In this case, the tender could also provide for the operation of government-owned vessels for several years.

Keeping the above in mind, we **recommend** that:

---

**14.2 In the case of those ferry services provided as a result of constitutional obligations, the governments concerned reassess arrangements and implement one of the following options:**

**(a) phasing down the capital and operating subsidy over 10 years to the minimum level consistent with continued operation of the service and with any other constitutional constraints; or**

**(b) offering a federal grant to the affected province in lieu of the subsidy. Such a grant might be based on the least-cost method of meeting the constitutional commitment. This would allow the province to decide if subsidizing ferry service was the best use of the funds.**

---

To encourage an appropriate balance between fare increases and cost reduction efforts, we suggest that users of subsidized ferry services be given opportunities to advise the ferry operator on costs and fares. In providing their advice, we ask them to recognize the subsidy constraints faced by the operator and the need for procedures to achieve full cost recovery, or reduction or elimination of services.

In addition, we **recommend** that:

---

**14.3 Where a ferry service provided as a result of a constitutional obligation is commercially non-viable, taxpayers provide the subsidy — not users of other ferry services through cross subsidies.**

---

Those responsible for making and applying the rules and spending the taxpayers' money should be accountable for their actions. If government decides to continue subsidizing a ferry service, for whatever reason (for example, regional development), the decisions should be transparent, that is, visible and up-front.

Therefore, we **recommend** that:

**14.4 The amount of, and reason for, any subsidy for a ferry service be clearly reported.**

# ENDNOTES

1. British Columbia Ferry Corporation, *Annual Report 1990-1991*, p. 3.

2. Two of BC Ferries' most highly used routes carried more passengers than did the other systems combined. These are the Tsawwassen to Swartz Bay and the Horseshoe Bay to Nanaimo routes, which carried approximately 5.9 million and 3.8 million passengers, respectively, in 1990.

3. Geoplan Consultants Inc., *Canadian Ferry Costs and Industry Analysis*, a report prepared for the Royal Commission on National Passenger Transportation, RR-09, December 1991.

4. Société des traversiers du Québec, *Rapport d'activités, 1990-1991*, Table 1.

5. Ontario Northland Transportation Commission, Planning and Development Office.

6. Geoplan Consultants Inc., Tables 3.1, 4.1 and A.1 to A.5.

7. For a more detailed discussion, see Patrick J. Monahan, "Transportation Obligations and the Canadian Constitution," in Volume 3 of this report.

8. See Transport Canada, "Subsidy Agreement between the Government of Canada and the Government of the Province of British Columbia," April 18, 1977.

9. Transport Canada, *1992–93 Estimates, Part III, Expenditure Plan* (Ottawa: Supply and Services Canada), pp. 3-30.

10. Transport Canada, "Subsidy Agreement," section 5.

11. Ibid., section 4(2).

12. Ibid., section 4(3).

13. The relevant term in the *Prince Edward Island Terms of Union* provided for: "Efficient Steam Service for the conveyance of mails and passengers, to be established and maintained between the Island and the mainland of the Dominion, Winter and Summer, thus placing the Island in continuous communication with the Intercolonial Railway and the railway system of the Dominion."

14. *Newfoundland Act*, R.S.C. 1985, Appendix II, no. 32.

15. The wording of these terms is as follows:

    32(2) For the purpose of railway rate regulation the Island of Newfoundland will be included in the Maritime region of Canada, and through-traffic moving between North Sydney and Port aux Basques will be treated as all-rail traffic.

    32(3) All legislation of the Parliament of Canada providing for special rates on traffic moving within, into, or out of, the Maritime region will, as far as appropriate, be made applicable to the Island of Newfoundland.

16. This section is based on the report by Geoplan Consultants Inc. entitled *Canadian Ferry Costs and Industry Analysis*.

17. The total of $147 million includes $26 million that is shown as depreciation. The federal government funds Marine Atlantic's capital requirements directly. Depreciation is shown to reflect a capital cost on the assumption that depreciation, in the long run, will equal capital advances.

18. The financial assistance provided to BC Ferries by British Columbia taxpayers is applied initially to cover any operating loss and, secondly, to a capital subsidy account. From 1989 to 1991 the provincial government provided $51 million annually. Since 1991, the annual subsidy amount has been negotiated by the province and BC Ferries, and has been reduced somewhat for 1992.

19. Peak season activity is defined as the volume of passenger auto equivalents moved in July and August. A passenger auto equivalent is used to measure deck space utilization to allocate costs to freight and passenger movements.

# CHAPTER 15

# INTEGRATING THE MODES

## INTRODUCTION

As part of our mandate, the Government of Canada asked us to inquire into and report upon a national intercity passenger transportation system that would be integrated. In our Interim Report we noted that, "For some Canadians, the ideal passenger transportation system is one that integrates different modes of transportation. . . . Many Canadians would like to choose between a variety of modes of travel for a trip and be able to move between these modes easily."

Canadians spoke to us about three types of intermodal connections that they consider desirable:

- multimodal terminals — that is, terminals shared by several modes;
- improved linkages from terminals to downtown or home, including baggage handling; and
- integrated reservation and ticketing systems, including multimodal travel packages.

## INTEGRATION TODAY

In Canada, with rare exceptions, the only form of intercity transportation that takes people and their luggage directly from home to destination is the car. Rail, airplane, bus — all rely on each other or on the car to deliver most travellers to their destinations. Virtually all the terminals of the public modes are designed around the car.

There are many other reasons for the limited integration of public intercity passenger transportation. To some extent, the problems of intermodal passenger transportation result from governments having introduced safety and economic regulations along modal lines. While such regulations make administrative sense for technologies and markets, they have tended to keep the modes apart. Also, integration is held back because carrier managers do not want to be dependent on other modes whose operations they may not fully understand or with which they are in competition.

We believe that intermodal connections for public passenger transportation can be improved. We note the way freight is transported in Canada, where we see an industry with increased integration and competition among intermodal services. Rather than operating in isolation, the modes that handle freight cooperate extensively to offer shippers convenient and speedy service. The smooth flow of goods depends on a network with good connections between modes, and on sophisticated management, including computerized capacity scheduling.

So what is causing the lack of integration in the passenger transportation system? In our study of intermodal transportation, we found some good examples of integration, some examples where the missing link between modes is simply lack of information on schedules and tickets, and others where the lack of coordination is not logical. We examined these situations and others, focussing our attention on those aspects of passenger transportation that might inhibit intermodal cooperation: regulatory restraints, industry reluctance, lack of government cooperation or planning, and gaps in transportation infrastructure (such as rail tracks that run right by airports but do not connect with terminals).

To be successful, intermodal connections require cooperation among carriers. Two operators of different modes sharing a terminal, but operating independently and with no effort to coordinate schedules or ticketing, are not achieving intermodality. A network of several modes with a common reservations system, common ticketing, coordinated schedules and effective transfers of people and baggage between modes may integrate successfully without sharing a terminal.

Carriers tend to favour intermodal connections when the modes complement one another (intercity buses connecting with urban transit, for example) but dislike intermodal connections when the modes compete with each other (intercity buses competing with intercity rail, for example).

***Canada's Busiest Intercity Passenger Service is Intermodal***

**The 44-km BC Ferries service between Victoria (Swartz Bay) and Vancouver (Tsawwassen) carries six million passengers annually. Many of these are car travellers while others make the full trip by bus. But others find it convenient to travel by car, then ferry and then bus. The bus service also connects (via a suburban hotel) with a shuttle service to Vancouver airport.**

**Bus tickets may be purchased aboard the ferries, and foot passengers who indicate their intention to continue by bus may deposit their luggage as they enter the ferry terminal. Their baggage is then transported to the bus by ferry staff for delivery at the passenger's destination bus terminal.**

## AIRPORTS — MOST INTEGRATION OCCURS HERE

In Canada, the most common form of intermodal integration is ground transportation at airports. Airports are usually located far from central business districts and urban transit systems. Making airports more accessible to passengers is thus a challenge. At Transport Canada airports, the rights to provide ground transportation are sold through competitive tender.

Private cars account for the largest proportion (65 percent)[1] of airport passenger arrivals and departures. Some travellers are dropped off and picked up; others park at the airport. Five percent of travellers rent cars at their destination airport.

Taxis and limousines provide convenient service to and from airports, but are the most expensive mode of public ground transportation. Nationally, they account for 15 percent of arrivals and departures. In general, taxi fares are regulated and taxis either pay the airport for the right to pick up passengers, or Transport Canada charges the local government for the costs to the airports associated with taxi operations. As an example of the former, Transport Canada charges over $4,000 annually per taxi for an airport taxi permit at Toronto's Lester B. Pearson International Airport. Due to the restricted number of permits, each has a market value in excess of $40,000. At Calgary, however, the city pays the airport for all taxi-related costs, which are estimated to be about $60 per taxi per year and any Calgary taxi may operate to and from the airport.

Taxis with municipal licenses may take passengers to airports; Transport Canada licenses taxis to pick up passengers from the airports. In cases where not having both licences causes taxis to make the return trip empty, the cost of taxi service is increased. Some hotels provide guests with courtesy vehicle service. These vehicles, which carry about 5 percent of passengers, pay airport licence fees equal to about one third of those charged to taxis.

Municipal buses providing links to central business districts are the cheapest form of ground transportation at airports. Airport employees are the predominant users of the local bus services (at Pearson, about a fifth of them do so). These buses, which carry a very small percentage of air passengers, are part of the municipal transit system and do not generally pay airport fees, nor do they handle baggage. Express bus services, which are licensed by Transport Canada, are generally used by passengers (about 5 percent), are more expensive and provide baggage service.

Out-of-town ground services, which include door-to-door vans and intercity buses, carry about 5 percent of airport passengers. Provincial boards regulate entry and the level of fares for these services. A Transport Canada permit, for which a concession fee may be charged, is also necessary.

### ***Exclusive Concessions at Transport Canada Airports Reduce Competition***

**In 1991, Greyhound Lines of Canada applied for a permit to serve Calgary airport, which is owned and managed by Transport Canada. Their application stated that the company could provide airport passengers with convenient connections, via Greyhound's other routes, to neighbouring communities.**

**Transport Canada rejected the Greyhound proposal, deciding that the existing shuttle service to downtown Calgary, provided by a local carrier, was satisfactory.**

Airport-to-rail intermodal connections do not exist, except to a limited extent at Montreal's Dorval airport, or via a bus link as in Toronto.

Many of these services suffer from a lack of visibility at airports, and information on schedules and fares is not always easy to find. Baggage handling and pre-boarding clearance are rare. Cash is often the only means of payment, and through ticketing is usually unavailable.

When we examined the charges for ground transportation at Transport Canada airports, we found that they are inconsistent with the department's cost-recovery policy for federal airports. Given their revenue objectives, it is logical that airport management favours private operators (which pay for concessions) over public buses (which do not). What seems inconsistent is that, at Pearson, while taxis without airport licences are charged a fee for a pre-arranged pickup, there is no charge to private cars for pickup and drop off of passengers. This situation is not exclusive to Pearson. At other airports, different means are used to charge for access by taxis and buses, but no fee is charged for access by private cars. Since urban buses pay no airport fees, they receive the lowest priority for platform accessibility.

### *Many Connections at Pearson Airport*

About 42,000 passengers arrive at, or depart from, Toronto's Lester B. Pearson International Airport every day, using different modes of transportation:

*Car:* Approximately 28,000 travellers use private vehicles. The airport provides 9,500 parking spaces supplemented by private off-site parking with shuttle-bus service.

*Toronto transit:* Three urban bus routes connect through the airport, each with two or three departures hourly, some linked to the subway system.

*Taxis, limousines, vans and intercity buses:* 550 taxis and limousines and 14 door-to-door van services and intercity bus companies offer scheduled and non-scheduled service to more than 50 centres throughout southern Ontario.

The public carriers serving communities beyond the Toronto metropolitan area are members of the Airport Ground Transportation Association, which coordinates the flow of the carriers and their passengers. The airport permits access to all public carriers who have the approval of the provincial or city regulatory authority, subject only to availability of space.

*Rail:* Governments earlier concluded that rail, as a stand-alone system, would not be economically viable. They are once again studying a rail link as part of the regional (all modes) transportation network. Rail connections via the express bus are available.

Leisure travel is an example of carriers cooperating to provide intermodal connections. In the leisure travel market, bimodal and even multimodal all-inclusive flight, cruise, bus and train packages are standard. Examples include air-rail excursions in the Windsor to Quebec City Corridor, air-rail-bus packages to the Rockies, and tours that include west-coast and Arctic cruises.

***Leisure Travel and Intermodal Connections***

- **Air Canada's Freedom Flyers promotion includes a seven-day Greyhound Lines of Canada pass.**
- **The Experience Canada coalition includes bus, rail and air carriers.**
- **Canadian Airlines International and VIA Rail offer fly-rail packages to foreign tourists.**
- **Canadian Airlines International and Brewster Transportation provide a fly-bus inclusive ticket price to Banff.**

## INTERNATIONAL COMPARISONS

In other countries, intermodal connections often involve considerable government funding and/or regulation. National railway monopolies dominate intercity public passenger transportation in Europe. For example, in France, the government intervened to ensure that a Train à Grande Vitesse (TGV) rail connection was developed at Charles De Gaulle airport. In addition, European governments often do not allow bus services to compete with train services.

In Germany, Frankfurt airport has instituted a central baggage handling system to maintain control over intercarrier baggage transfers and to improve the convenience of the airport as a transfer point between air and rail. The airport's system allows convenient integration of the government-controlled airline with the government-controlled rail system.

Many foreign airports are connected to cities through rapid-rail transit. For example, the U.S. government funds the "Metro" in Washington, D.C., which provides express subway service to Washington's National Airport. About 15 percent of airport passengers use this transit system. A new transit line to the Atlanta, Georgia, airport is used by 10 percent of air travellers to Atlanta as well as by airport employees.

## BARRIERS TO INTEGRATION

It was clear to us that Canadians want more integration of transportation, and that the current passenger transportation connections among modes are often not well developed. Is poor integration simply the result of competition among commercial carriers? For example, carriers see the other modes as competitors rather than extensions of their service. For this reason, bus carriers do not want their passengers to have easy access to trains and therefore resist the use of a common terminal.

### THE CAR

We concluded that there are many reasons for Canada's lack of an integrated passenger transportation system. For example, Canadians' extensive use of motor vehicles discourages public mode integration. If cars and taxis did not provide transportation to and from terminals, intercity operators would have to cooperate with local public transit to provide door-to-door service.

### THE GOVERNMENT'S ROLE

Both the *National Transportation Act* of 1967 and the *National Transportation Act, 1987* called for free competition among the modes. The 1967 Act promoted competition between public modes to create an "economic, efficient and adequate transport system." The 1987 Act expanded competition from among the modes to within the modes and, at least for the air mode, lessened regulatory burdens and simplified regulatory procedures. The legislation does not encourage cooperation among carriers of different modes.

### COMPETITION

Although market forces may not be sufficient to encourage integration among competitors, we note that where there are a number of carriers and regulation of access to the market has been relaxed, intermodal connections improve. Historically, links to rail have been more frequent where there were competing bus lines. As further evidence, deregulation of domestic air transportation encouraged new entrants and prompted major air carriers to integrate their schedules with subsidiary and allied feeder air carriers.

The airlines that made submissions to us expressed an interest in extending this type of integration to surface modes. In addition, VIA Rail has consistently expressed interest in bus-rail terminals, believing they would result in a net gain in traffic for VIA Rail. While air carriers are interested in better surface connections, market-entry regulations — particularly those for intercity buses — make it difficult for new operators to provide such connections.

## REGULATION

The tightly regulated intercity bus industry poses obstacles to integration. Provincial regulations have created intercity bus route monopolies. In addition, intercity bus companies have generally been opposed to convenient bus-rail terminals. They believe they would lose profitable passengers to rail and only pick up less profitable or unprofitable feeder traffic.

Restricted access of ground transportation to air terminals hinders intermodal connections and traffic growth. In general, airports limit such access in order to generate revenue from concession permit holders. We are concerned that the federal government's current airport revenue policy creates pressure to obtain income from permits, and does not encourage airports to create and expand a wide range of ground transportation. We hope that the new federal policy of turning the management of federal airports over to local authorities will have a positive effect. We expect that local managers may give more weight to their communities' needs, to passenger convenience and to encouraging growth in passenger volume.

At present, computer reservation systems are confined to two modes. VIA Rail subscribes to the airlines' computer reservation systems, but bus companies do not because they find them too expensive. Greyhound has introduced an automatic central telephone system that offers not only information on its own schedules and fares but also information on other bus companies in the continental network. Expanding such information systems to include all modes would be a step toward an integrated passenger transportation system.

## DISMANTLING THE BARRIERS

In Chapter 13, we recommend major regulatory reform of the intercity bus industry to permit competition within that mode. The result of these new opportunities might be a market comprising intermodal chains of cooperating carriers. These chains would compete with each other, providing convenient origin-to-destination, single-ticket service.

For many travellers, modal integration means the ability to make easy interconnections among the modes. This encompasses through ticketing, flow-through baggage handling and minimizing of the number of interconnections.

Many told us that they find it incredible that, through the action of governments, Mirabel airport was located so far away from any city, and with so few means of public access. In addition, many large airports such as Pearson and Dorval are not connected to urban subway networks or to nearby rail lines.

While some of these past decisions may not have been good, it would be extremely expensive to make the desired corrections. Interconnection projects should be evaluated in accordance with our principles. Those responsible for assessment should recognize that terminals alone do not achieve intermodality, that connections among competing modes generally require intervention by governments, and that costs, including common costs, must be properly charged to the various users of the transportation system.

Multimodal terminals are an obvious way to encourage integration. We note, however, that land costs have been a major consideration in the location of bus terminals, and local governments usually participate in deciding the location of urban terminals. Passenger rail stations are generally located near urban transit connections and offer practical starting points for multimodal rail and bus terminals.

Direct government intervention, involving access to public terminals and possible funding of construction, might support more intermodal cooperation. We believe, however, that there are more cost-effective ways to advance modal integration. The role of government as mediator and coordinator, but not necessarily as banker, needs to be emphasized. We urge that a greater role be played by governments at the local level. Reform of regulatory restraints, location of terminals, integration of capacity and design with urban development and zoning functions, and selection of suitable urban terminal designs are issues for local resolution.

## RECOMMENDATIONS: MOVING TOWARD INTEGRATION

Under our principles, we favour opening all transportation markets to competition, including providing for non-discriminatory access to transportation terminals. We believe that applying our principles to passenger transportation would substantially increase the availability and convenience of intermodal travel.

### ACCESS TO TERMINALS

While market forces alone are unlikely to cause the development of major intermodal terminals, we note that terminals built by government do not guarantee better intermodal services. Unless there are large cost-savings, dominant carriers resist sharing terminals with their competitors.

## *Government and Multimodal Transportation Planning*

### *Mirabel, Quebec*

Planners recommended that Montreal's international airport be located in Hudson Heights, Quebec. Highway access and commuter rail service to Montreal and Dorval airport were convenient, as were highway access and passenger rail service to Ottawa.

For a variety of reasons, however, the federal government built the airport in Mirabel, north of the Ottawa River. Builders included a commuter rail station within the airport terminal. Governments believed that a rapid-transit connection would counter the inconvenience of the airport location and further stimulate economic development of the region. The transit system, however, was never built. The commuter rail station is not used and now provides parking for airport employees.

### *Calgary, Alberta*

In the 1970s and early 1980s, Calgary planned to attract foreign tourists by integrating several modes of transportation in one terminal. Included would have been intercity bus passenger services, VIA Rail, the city's new light rapid-transit system and a shuttle bus to the airport with a check-in facility for airlines.

Two competing bus companies, Greyhound and Pacific Western Transportation, were eager to co-locate with VIA Rail but not with each other. When railway passenger service between Calgary and Edmonton was discontinued in 1986, Calgary's multimodal terminal planning ended.

### *Kitchener, Ontario*

When its city council agreed that a catalyst was needed to revitalize Kitchener's downtown core, an urban/intercity bus transportation centre was chosen. The province of Ontario paid $3.8 million of the $10 million cost for the 28 bay terminal with parking and provision for a shopping mall. This multimodal transportation centre was opened in 1988.

Some interveners argued for public investment in multimodal terminals, saying that more travellers would choose public modes if transfers were more convenient. Although we have not found evidence to support this argument, it may be true. We do not believe, however, that building a terminal guarantees its effective use.

Scheduled urban bus transportation that links airports to cities can be found in such centres as Vancouver, Winnipeg, Toronto, Ottawa and Montreal. Direct rapid-transit links do not yet exist at any Canadian airport, nor are dedicated urban express bus connections as developed as they are in other countries. In many cases, public transportation services from the nearest airport to small cities are either infrequent or non-existent.

Bus companies told us that if Transport Canada's exclusive airport concessions to taxi and bus operators ended, the result would be increased services by the intercity bus operators. In addition, airlines might operate their own feeder buses. For service between airports and smaller communities, multiple-passenger taxi services, perhaps semi-scheduled, might be viable if they could pick up and deliver at the airports and were allowed unrestricted intercity operation. Eliminating licences and exclusive franchises would not, of course, require eliminating all charges for motor vehicle access to an airport, but these charges should be applied on an equal basis to private cars, taxis and buses.

We believe that levels of government must work together to improve air and ground connections while local authorities assume management of major airports.

Therefore, we **recommend** that:

**15.1 Airport and municipal authorities cooperate to ensure unrestricted access to airports by all ground connectors who pay their share of the costs, and federal authorities grant all ground connectors open access to federally owned airports and rail stations.**

**15.2 All agreements for the sale or lease of federal transportation infrastructure include provisions that oblige the operating authority to grant open access to all intermodal connectors on equal terms and conditions.**

## ANTI-COMPETITIVE PRACTICES

Reducing regulations and removing impediments posed by differing regulatory jurisdictions may create a market dominated by one or two large, sophisticated carriers. We believe that our recommendations on open access would reduce the likelihood of a monopoly. We recognize, of course, that when competition is replaced with cooperation, dominant carriers, or a consortium of carriers, may gain market advantages and engage in anti-competitive practices.

In addition, transportation information technology, such as computer reservation systems, will play an important role in integrating passenger transportation services. Market forces will encourage the growth and development of these technologies, which, if controlled exclusively by one or two carriers, could lead to anti-competitive practices. How the government chooses to regulate against abuse by powerful data monopolies could influence future development of public intermodal connections.

Therefore, we **recommend** that:

**15.3 To give all modes the opportunity to compete and to cooperate on an equal basis, the federal government extend its regulations governing the anti-competitive practices of computer reservation systems beyond the air mode to take a multimodal approach.**

We believe that travelling Canadians would benefit from using intermodal connections and reservation systems that encourage cooperation and integration among modes.

# ENDNOTES

1. The 65 percent for cars and corresponding percentages for the other forms of ground transportation are approximate, judgemental estimates based on information from a number of individual airports but not on systematic, comprehensive data.

# CHAPTER 16

# SEEING INTO THE SYSTEM: ACCOUNTABILITY AND TRANSPARENCY

## INTRODUCTION

In Chapter 4, we stated that those responsible for making and applying transportation regulations and for spending taxpayers' dollars should be accountable for their actions. We said that governments can improve such accountability through transparency — making relevant information available and understandable. We further recommended that decision making be transparent so that Canadians can understand why choices are made.

In this chapter, we look at ways to improve accountability and to ensure that transportation expenditures and the reasons for making them are available to taxpayers and travellers. We are concerned with:

- what data are needed; and
- how the success or failure of the passenger transportation system can be judged.

## WHAT CANADIANS TOLD US

### WHAT THEY WANT TO KNOW

In our Interim Report,[1] we noted that Canadians had told us that they were not happy with the accountability and transparency of the passenger transportation system. They were not convinced that they were being told, with any accuracy, how their money was being spent, and they could not make a fair comparison between the travel modes because subsidies and costs were hidden within the system.[2]

In view of this, they wanted a more complete accounting of costs so that they could more adequately compare all modes, especially when considering large expenditures for new and improved infrastructure. They would also like a clear accounting of the subsidies paid by governments to the different modes of passenger transportation.

### OBSTACLES TO TRANSPARENCY

Many who spoke to us recognized the difficulties in calculating the subsidies to each mode. These difficulties occur because:

- multiple levels of jurisdiction subsidize travel;
- governments report investment expenditures on air, road and water infrastructure as annual expenses that are, in turn, mixed in with annual operating expenses; and
- social and environmental costs are hard to measure.

Canadians asked us to do our best to help them understand how much money is being spent and how the levels of government are spending tax dollars on each mode. They asked for a comprehensive accounting of costs that would enable them to better evaluate transportation choices.[3]

## ACCOUNTABILITY

### BENEFITS OF NEW INSTITUTIONS

#### A Better Accounting of Costs

In Chapter 6, we recommended new institutions for managing the passenger transportation system. These new institutions would improve accountability and transparency because they would develop accounts differently from those maintained by federal, provincial and territorial departments of transport, and would report income and expenditures in a more business-like way. For example, such institutions would regularly record investments in physical assets on a balance sheet — not as a current operating expense.

### More-Visible Subsidies

The new institutions would be separate from government and would have a corporate structure. The result would be that, if a government decided to finance an activity that does not pay its way, that government would have to make public any subsidies paid for that activity. For example, if a government decided to build a road that did not meet the investment criteria of the road agency, it would have to pay the road agency to undertake the project, and the subsidy would be visible to the public in the government's accounts.

Throughout our report, we have recommended that governments make public not only the amount of subsidies, but the reasons for providing them. We believe that such information is necessary if taxpayers are to hold their governments accountable.

## RECOMMENDATIONS FOR ACCOUNTABILITY

We also believe that, where agencies provide transportation infrastructure as monopoly suppliers, travellers and other interested parties should have a say in major decisions.

Therefore, we **recommend** that:

**16.1 Where an agency providing transportation infrastructure is a monopoly supplier, the level of government responsible for the agency create an advisory body of travellers and other interested parties to counsel management on investment priorities, charging mechanisms and appropriate charges for achieving financial self-sufficiency.**

Governments should be accountable in their roles as regulators and referees, as should government agencies who are monopoly suppliers of transportation infrastructure. Governments, therefore, must ensure that:

- objectives for such Crown corporations are clearly stated;
- information is available to allow taxpayers to assess the degree to which objectives have been met; and
- those responsible for making decisions are judged on their achievements.

## THE NEED FOR MORE AND BETTER INFORMATION

At present, there is a great deal of data available about Canada's passenger transportation system. During the course of our studies, however, we discovered many areas in which the data were not adequate to answer the questions we were mandated to investigate.

### WHAT CANADIANS NEED TO KNOW

Data collection should meet the needs of users and other interested parties, such as ministers, government officials and carriers. To determine what information is necessary, we asked whether more or improved data are necessary to:

- predict what will happen to the system if a decision is taken to change it, or if the status quo continues;
- estimate the benefits and costs of proposed changes to the system; and
- evaluate the effects of a policy or program after it has been put in place. (In this case, the information should include the measurement of outputs as well as inputs. At present, governments rarely report on whether or not the programs' objectives have been achieved.)

## CURRENT DATA GAPS

We identified several areas in which there are little or no data on the passenger transportation system. Table 16-1 shows where data gaps exist and how missing data would be used. The table indicates:

- what type of data is needed;
- the type of decision for which the data would be used;
- the contribution of such data in assisting people to participate in decision making;
- the difficulty of obtaining the data (the cost and the burden placed on those who must collect and report the information); and
- whether the gap is primarily one of data collection, estimation or analysis.

*Table 16-1*
*CURRENT DATA GAPS*

| Type of data gap | How data would assist in making policy decisions | Contribution of data to accountability | Costs or burden | Action needed |
|---|---|---|---|---|
| **Comprehensive coverage of services offered (frequency and points served) and prices.** | To study the impacts of regulatory changes.<br>To assess the adequacy of competition. | Good price and service data are key indicators of consumer impact. | Raw data are publicly available from the carriers, but data-base management would be required. | Data assembly and collation. |
| **Information on public infrastructure and capital stock.** | To provide a cost base for infrastructure pricing.<br>To indicate the adequacy of replacement investment. | It will ease the evaluation of previous decisions, improve the transparency of capital costs and allow public capital costs to be compared with those of the private sector. | Establishing appropriate depreciation costs could be complex in some situations. | Estimation of depreciation, collection of data for existing projects. |

*Table 16-1* *(cont'd)*

**CURRENT DATA GAPS**

| Type of data gap | How data would assist in making policy decisions | Contribution of data to accountability | Costs or burden | Action needed |
|---|---|---|---|---|
| **Information on environmental impacts and costs.** | To provide a basis for environmental charges and/or regulatory constraints.<br>To help choose which mode to invest in when alternatives exist. | These data would help transportation policies to achieve environmental goals. | The costs would vary depending on the nature of the data required.<br>The additional burden may be minimal if the data are also being used for an environmental assessment. | Evaluation of environmental damage and collection of data on environmental impacts. |
| **Data on system use and volumes (especially for road travel).** | To determine the demand for expansion when judging new projects.<br>To allocate costs and design pricing policies appropriately.<br>To assist in intermodal planning. | It will be used in evaluating projects and estimating the benefits of new or similar projects. | This may not be costly, either financially or in terms of response burden, if existing or modified highway counting systems can be used. | Data collection. |
| **Information on the origin and destination of trips. (There is a large gap in highway data and some improvement needed in other modes.)** | To provide background to assist in infrastructure investment and intermodal integration.<br>To perform demand modelling. | This information would be helpful for understanding intermodal flows. | The collection of these data would be costly, and would require individual surveys. | Data collection. |

## RECOMMENDATIONS FOR DATA GATHERING

It is important that the data systems that we have begun to develop (in particular the estimates of costs of the passenger transportation system including environmental damage, safety and accident costs) be added to for future use and that data gaps be filled.

Therefore, we **recommend** that:

**16.2 Governments allocate resources to the continuing improvement of travel and other transportation data and the data be available to the public.**

**16.3 Provincial and territorial governments cooperate with the federal government to ensure the collection of data for modes within their jurisdictions.**

## TRANSPARENCY

Better data would improve accountability, but would not necessarily ensure that passenger transportation decisions were more visible to Canadians.

We believe that Canadians should have access not only to information but to the reasons behind decisions that affect them as taxpayers and travellers.

Therefore, we **recommend** that:

---

**16.4 The federal government publish an annual report card on the passenger transportation system to include such information as:**

**(a) who uses the transportation system and how much;**

**(b) the amounts and proportions paid by travellers, carriers and taxpayers;**

**(c) why, to whom and by whom subsidies if any are given;**

**(d) the reliability of the passenger transportation system;**

**(e) the safety of the passenger transportation system;**

**(f) the costs not recovered from travellers and carriers for such activities as policing highways, providing medical assistance for victims of traffic accidents, and repairing environmental damage caused by the transportation system; and**

**(g) the degree to which passenger transportation policy, and regulatory and expenditure decisions meet stated objectives.**

---

# ENDNOTES

1. *Getting There: The Interim Report of the Royal Commission on National Passenger Transportation* (Ottawa: Supply and Services Canada, April 1991), pp. 156-57.

2. Such subsidies and costs certainly include expenditures for policing highways, providing medical assistance for victims of traffic accidents, and repairing environmental damage caused by the transportation system. They would also, in principle, include any tax expenditures specific to transportation such as capital subsidies for the purchase of transportation equipment.

3. Two examples of improved transparency are the New Zealand Land Transport Fund and the Swiss Road Account. See New Zealand Ministry of Transport's "Land Transport System" and Francis-Luc Perret and P.A. Jaccard, "The Swiss Road Account," in the European Conference of Ministers of Transport, *Report of the Eightieth Round Table on Transport Economics on Systems of Road Infrastructure Cost Coverage,* Paris, February 1989.

# CHAPTER 17

# IMPLICATIONS FOR INTERNATIONAL COMPETITION AND FOREIGN OWNERSHIP

## INTRODUCTION

Policy changes in transportation, as in other sectors of the economy, may affect Canada's economic relations with the rest of the world, particularly the United States, Canada's major trading partner. In the first part of this chapter, we discuss the potential effects that new charges for transportation infrastructure, environmental costs and accident costs will have on Canadian carriers who face international competition.

This chapter also considers, within the context of our principles, the issues associated with foreign ownership and entry of foreign-owned carriers into the Canadian market. We explored aspects of these issues in the discussion of international air policy in Chapter 11. In this chapter, we provide a broader review of how the application of our principles to all modes might affect international competition and investment, including foreign ownership.

## TRANSPORTATION CHARGES AND INTERNATIONAL COMPETITION

Since many Canadian carriers are in competition with foreign carriers, we asked:

- If travellers must pay increased transportation charges, would such increases put Canadian carriers at a disadvantage with foreign competitors?
- Should concern about potential competitive disadvantages constrain the extent to which governments shift transportation costs from taxpayers to travellers?

- In previous chapters, we urge governments to consider the extent to which they treat the modes differently with respect to direct and indirect subsidies and taxes, because these differences may affect the ability of one mode to compete with another. Should governments be equally concerned that the treatment of a particular mode in Canada is different from the treatment of the same mode in other countries, particularly in the United States, where transportation subsidies are extensive?

In examining these questions, we asked more specifically:

- In what circumstances would higher charges create a competitive disadvantage for Canadian carriers?
- Where there is such disadvantage, in what circumstances would it affect the efficient functioning of the Canadian economy?

## SITUATIONS WITH NO COMPETITIVE DISADVANTAGES

We believe there are many situations in which higher charges in Canada will not affect the ability of Canadian carriers to compete with foreign carriers. This is either because such competition does not exist, or because foreign carriers also would be subject to Canadian charges when they provide services that compete with Canadian carriers. Two examples follow.

*Domestic services:* Higher charges do not affect competition on those domestic services where travellers have little choice of alternative routes through the United States — for example, a trip from Calgary to Edmonton. International competition would also likely be unimportant on trips from Toronto to Montreal, and probably the majority of domestic routes. In some cases, however, the higher costs of a domestic trip might influence a traveller, particularly a tourist, to shift to a foreign destination. The result would be some adverse effects for Canadian suppliers of tourist services, and possibly for Canadian carriers.

*Trans-border services:* Higher fuel charges would probably have little effect on the competitive positions of Canadian and foreign carriers. Both groups of carriers face similar needs and opportunities to obtain fuel during the Canadian and foreign portions of their routes. Similarly, higher road tolls, airport landing charges and air navigation fees, which are also directly related to distance travelled or infrastructure used within Canada, would have little effect on the competitive position of Canadian carriers. Higher annual licence fees, however, could put Canadian carriers at a disadvantage unless foreign carriers face a comparable charge in relation to their use of Canadian infrastructure.

It is important to structure Canadian transportation charges so that they apply equally to Canadian and foreign carriers on routes that are entirely or partially in Canada. If equal charges are not possible (for example, if foreign carriers have better access to cheaper fuel than domestic carriers do), then special measures may be necessary. Foreign carriers may have to pay the equivalent of the Canadian charge, or governments may have to make less use of the specific charge.

## SITUATIONS WHERE COMPETITIVENESS IS AFFECTED

In some cases, a route through another country — primarily the United States — can serve as an alternative to a Canadian route. The result is that a foreign or Canadian carrier can avoid the higher Canadian charges associated with the Canadian route. For example, a Vancouver to Toronto air traveller might take two flights involving a U.S. stopover, or might take ground transportation to nearby U.S. airports and fly from the United States. Rerouting via the United States, as a result of higher Canadian charges, could affect Canadian air travel and have a substantial impact on Canadian carriers.

We do not believe there is any gain in keeping traffic in Canada that does not cover costs. For example, raising charges on trucks to cover the costs of wear on Canadian highways might cause some truckers to use U.S. routes with lower charges that do not cover the cost of road wear. If Canadian governments set charges to truckers low enough to retain the traffic in Canada, the gains to the economy from the charges, even with higher traffic, would not cover the costs of road wear; general taxpayers would therefore have to make up the difference. While the competitive position of Canadian truckers may suffer as a result of such higher road charges, maintaining a competitive position through a form of subsidy — charging less than costs — will not benefit the Canadian economy.

Similarly, if a carrier ceases to be competitive when it faces the full costs of its accidents and environmental damage, the Canadian economy is not likely to benefit from maintaining activities that cannot cover these costs.

There are two situations, however, where traffic diverted as a result of Canadian charges could involve a net loss to the Canadian economy: when environmental charges are based on global damages, and when transportation infrastructure charges are substantially higher than marginal costs.

### When Environmental Charges are Based on Global Damages

If Canadian charges for environmental damage are based, not on damage in Canada, but on global damage, diverted traffic may result in a loss to Canada and little gain to the world. For example, Canada could impose a fuel charge for carbon dioxide ($CO_2$) emissions that is much higher than the charge imposed in the United States. The result could be lower revenues for Canada when traffic shifts to the United States and no environmental benefit to Canada or the world. There would be no reduction in $CO_2$ released, only a shifting of emissions out of Canada to the United States.

Although Canada may wish to show leadership in responding to global environmental problems, it will pay an economic price if it moves much ahead of other countries in pursuing such environmental objectives, either through higher charges or through stricter regulatory standards.

In Chapter 7, we identify global warming as a multinational issue and recommend that Canada strive to obtain international agreement on strategies that coordinate national policies and charges aimed at reducing global warming. It would not be appropriate for Canada to differ greatly from competitors in those environmental policies where the benefits of Canadian action are not concentrated in Canada but are global, and where the real benefit to Canada depends not on Canadian action but on global action. Canadians, however, should not lag behind the rest of the world in meeting their responsibilities in reducing global pollution.

### When Transportation Infrastructure Charges are Substantially Higher than Marginal Costs

In Chapter 5, we examined situations in which transportation infrastructure charges may have to be substantially above marginal costs to achieve full cost recovery. In such cases, the value of the benefits received by a group of users should be a factor in determining the extent to which charges are in excess of marginal costs.

In a hypothetical example, the marginal cost associated with providing air navigation services for a passenger aircraft on a Vancouver to Toronto flight could be $100, but a charge of $300 has been set as part of recovering the costs of the air navigation system, since many of its costs do not vary proportionately with use. If such a charge results in an aircraft shifting from a Canadian to a U.S. route, Canada loses $300 in revenue but avoids only $100 in costs. Clearly, if it results in a substantial shift of traffic to the United States, this charging scheme will not be successful in recovering full costs.

In Chapter 5, we described our approach to pricing, in which some infrastructure charges take account of the value of benefits received. In applying that approach to our hypothetical example, one should recognize that:

- The alternative U.S. route reduces the value of the benefit of the Canadian air navigation system to the aircraft operator, who can make use of the U.S. route.

- Because the operator would not value the Canadian infrastructure as highly, the operator's desire to use the Canadian infrastructure would be more responsive to price than that of an operator who had no alternative.
- Therefore, operators in a position to substitute use of foreign infrastructure for a Canadian one should not be charged as high a mark-up over marginal cost as those who have no choice.

We recognize that foreign charges on competing routes and infrastructure do constrain the extent to which transportation charges in Canada should exceed marginal costs. We note, however, that the United States and other countries are changing the way they are charging for their transportation systems.

## CONCLUSION

From our review of transportation charges and international competition, we conclude that:

- The appropriate starting point in setting charges for infrastructure, environmental damage and accidents is still the efficient costs associated with use in Canada for the different modes, rather than the level of foreign charges for the modes.
- Under our principles, net increases in charges to air and car travellers for transportation infrastructure, accidents and environmental damage would generally not be large relative to the overall cost of travel currently borne by travellers (Chapter 18). In addition, such increases would, in part, be offset by the gains that travellers experienced as a result of the new institutional arrangements that were more responsive to their needs, and provided better service.
- In many cases, the absence of foreign competition or the equal treatment of foreign and Canadian competitors, means that the competitive impact of Canadian charges compared with foreign charges would not be significant. Governments should be careful to design charges so that they apply equally to Canadian and foreign carriers using the same routes.

- There are situations, especially where there is a choice between a Canadian route and a foreign route, when the charges may affect the competitive position of Canadian carriers or may affect the route chosen by both Canadian and foreign carriers.
- Even if Canadian charges affect the competitive position of Canadian carriers, Canada's economy will not likely benefit when charges are set below marginal costs.
- There are two situations in which charges are set above marginal costs and in which the level of foreign charges should constrain Canadian charges.

  The first occurs when an environmental charge is based on global damage rather than on damage in Canada. It would be costly for Canada to impose higher charges than those imposed by its major trading partners. We strongly support international coordination of environmental policies and charges.

  The second occurs when transportation infrastructure charges are set above marginal costs to recover infrastructure costs fully. The ability of a group of travellers to substitute use of foreign infrastructure for Canadian infrastructure will constrain the extent to which charges can be raised above marginal costs.

## FOREIGN OWNERSHIP

Under our proposals, any competitor who is "fit, willing and able" to supply passenger carrier services should have an opportunity to do so. We do not distinguish whether the competitor is a domestic or a foreign carrier. In transportation, as in other sectors of the economy, foreign competition can contribute to lower costs and improved product quality. Foreign carrier entry can be particularly important in those markets where actual and potential domestic competition is weak or absent.

Foreign carrier entry into the Canadian market may involve establishing a new Canadian base of operations by the foreign carrier, or acquiring a Canadian carrier. Restrictions on either form of entry may reduce competition and pressures for efficient performance. Restrictions on foreign ownership could also result in a carrier being taken over by an existing domestic carrier, leading to a substantial increase in market concentration. In addition, controls on foreign ownership may prevent a firm from being integrated into a larger multinational operation and realizing major gains in efficiency.

At the same time, trade barriers — which Canada is not in a position to eliminate through its actions alone — prevail in world markets for some transportation services. These barriers should be taken into account when judging Canadian trade and foreign ownership policies.

## AIR CARRIERS

As discussed in Chapter 11, today Canadian air carriers can enter foreign markets only through government-to-government negotiations in which foreign carriers are simultaneously offered increased access to Canadian markets. Unilaterally opening Canadian markets by giving landing rights to foreign carriers, in effect "giving away our bargaining chips," would foreclose opportunities for Canadian carriers to gain entry into new foreign markets. As we noted in Chapter 11, giving landing rights could also lead to the creation of monopolies on certain important international routes. A foreign government may be inclined to take advantage of the resulting opportunity to designate its national airline as the sole carrier on major routes to and from Canada.

We conclude that, in general, the federal government should not depart unilaterally from the special rules of government-to-government negotiation that characterize international air services. We recognize, however, that this approach may conflict with the need to maintain competition and ensure that air travellers are provided with low-cost, reliable service. Recommendation 11.6 and the final section of Chapter 11 on Open Skies address those situations where the benefits from new entry justify a departure from the traditional approach toward foreign ownership and competition in the airline industry.

## RAIL CARRIERS

Passenger rail carriers generally operate within the borders of their home countries. This is true for VIA Rail in Canada and Amtrak in the United States, with the following exceptions:

- VIA Rail routes between Montreal and Halifax pass through Maine; and
- Amtrak uses Canadian track on its services into Toronto and Montreal and, in collaboration with VIA Rail, provides some domestic service in southern Ontario.

We do not believe that there is reason to restrict access to Canadian track by a foreign-owned rail carrier as long as the foreign carrier pays appropriate charges and is governed, while operating in Canada, by the same rules that govern Canadian-owned carriers.

## BUS CARRIERS

Most companies in Canada's regulated intercity bus industry are domestically controlled. An exception is the country's largest carrier, Greyhound Lines of Canada Ltd., which is controlled by U.S. shareholders. Greyhound Canada's intercity bus operations earned about 40 percent of total industry revenue in 1989, or about three times as much as the next-largest intercity bus carrier. Our recommendations in Chapter 13 would benefit Canadian travellers by easing entry into the industry for both Canadian-controlled and foreign-controlled firms. The result would be a competitive environment that encouraged bus companies to innovate, reduce costs and improve service.

Bus carriers from the United States seeking entry into Canada would be subject to similar "fit, willing and able" criteria as Canadian carriers seeking to compete in those U.S. jurisdictions that have eliminated economic regulation. Many states in the United States continue to restrict entry into their intrastate markets. The United States *Bus Regulatory Reform Act, 1982*, however, deregulated interstate busing and allowed the Interstate Commerce Commission to grant interstate carriers the right to serve points within a state on a new or existing interstate route.

We encourage the federal government to press for a relaxation of entry restrictions into those U.S. states that continue to impose economic regulation. Whatever emerges from such negotiations, however, we believe the interests of Canadian travellers are best served by relaxing provincial entry controls that apply to all firms, foreign as well as Canadian-owned.

## FERRY CARRIERS

There are no Canadian restrictions on the ownership or control of ferry services. Restrictions do exist on the vessels that may be used to carry passengers between two Canadian ports, but such restrictions are designed to protect the Canadian shipbuilding industry, not the ferry operators. (Domestic water transportation is reserved for Canadian-registered ships. Foreign-registered vessels are subject to a substantial customs import duty, unless a waiver can be obtained owing to the lack of a suitable Canadian-registered vessel.) By contrast, the United States is highly protective of its carriers. Under the *Jones Act*, only U.S.-owned ferries can transport passengers between two ports in the United States. We believe this is an inappropriate model for Canada. Foreign ownership and entry restrictions are not consistent with our principles and are not in the long-term interest of Canadian ferry users.

In all modes, Canada will benefit from foreign competition as long as foreign carriers operating in Canada are governed by the same regulations that govern Canadian carriers.

# CHAPTER 18

# ADDING IT ALL UP: PASSENGER TRANSPORTATION COSTS — TODAY AND TOMORROW

## INTRODUCTION

In this chapter, we provide estimates of the costs of transportation today and how we expect our principles to affect these costs in the future. To demonstrate how our recommendations would change costs, Tables 18-1 to 18-4 show:

- what is paid today, and by whom;
- what would be paid in the year 2000, and by whom, if governments do not change current transportation policy; and
- what would be paid in the year 2000, and by whom, if governments implement the recommendations in this report.

We want to stress that our recommended changes in charges to travellers are not an "add on" to existing fees, charges and taxes paid by Canadians. Canadians are already paying all the costs of transportation in some way. Increases in charges to travellers will be offset by making available billions of dollars annually that governments can use to lower taxes. As well, our charges to travellers are based on the provision of an efficient level of services and infrastructure, not "gold-plated" ones — you get what you pay for and only pay for what you get.

All estimated costs, for today and for the future, are in 1991 dollars. We did not build in estimates of inflation in the general level of prices that may occur between 1991 and 2000. We believe that giving costs in same-year dollars provides a better comparison.

We ask readers to understand that the costs in the tables and the text are not precise estimates, but are rough indications of the direction and magnitude of change and of the differences among the costs by mode. Providing precise estimates of future passenger transportation costs is beyond the scope and resources of the Royal Commission. When governments implement our recommendations, producing more precise estimates will require a substantial amount of work.

We cannot forecast with any precision how the Canadian population, economy and society will develop over the coming decades, or how the location of activities and the demands for intercity travel might alter. We do expect that intercity travel will continue to grow faster than the population and general economic activity, probably doubling each generation, and that long-distance travel, particularly by airplane, will grow faster still. Governments will implement our recommendations against this background of continual change. Our recommendations, in turn, will bring about further changes.

We do not believe that it is necessary to have precise forecasts to be confident that the effects of our recommendations will be beneficial. Under our principles, carriers and travellers will pay the full costs of travel. The result will be that they use transportation resources more efficiently in their choice of trips, modes and routes. For example:

- Transfer of road costs from taxpayers to car and other motor vehicle users will affect car use, causing consolidation of trips and — everything else being equal — shifts to other means of travel. There will be some encouragement of denser patterns of land use and of slower growth in car ownership.
- Reduction of fares on buses, following relaxation of economic regulation, will stimulate bus use, with some travellers switching from other means of travel and others making bus trips they would otherwise not have made.

- Charges for environmental damage will lead consumers to use cars that cause less damage, and may lead car makers to manufacture less-polluting cars.

The resulting changes in total travel and in the share of each mode will depend on many factors that interact in subtle and complex ways. We cannot forecast all the changes that will occur and their impact on transportation costs. But we can predict the major changes that will affect transportation costs for travellers, carriers and providers of infrastructure.

## COSTS FOR ILLUSTRATIVE ROUTES

We present illustrative costs for four intercity routes that represent different types of travel by length, passenger volume and carrier type. The costs are not specific to the routes, but are based on average costs for the type of service and distance.

***Four Illustrative Routes***

- **Saskatoon to Halifax: a long-distance route consisting primarily of medium-volume segments.**
- **Toronto to Montreal: a high-volume, medium-distance route.**
- **Churchill to Winnipeg: a low-volume, medium-distance route with no continuous road.**
- **Halifax to St. John's: a medium-volume, medium-distance route that may include ferry travel.**

## READING THE TABLES

The following categories of transportation costs are shown in each route table:

***Types of Transportation Costs***[a]

| | |
|---|---|
| **Infrastructure:** | **costs of terminals, links and traffic control systems not provided by carriers.** |
| **Environmental:** | **costs of environmental damage associated with vehicle/carrier opertions.** |
| **Accident:** | **costs of death, injury (including health care costs) and property damage associated with transportation accidents.** |
| **Special Tax/Fee:** | **costs of fuel taxes and vehicle, carrier and drivers' licences.** |
| **Vehicle/Carrier:** | **costs of vehicles and carrier services.** |

**a. For more-detailed information on types of transportation costs, see Chapter 3.**

The three blocks in the route tables with three columns in each block illustrate transportation costs in the following manner:

- "1991" shows current costs by means of travel. These figures are calculated on the same basis as the estimates in Chapter 3, and are identical to the Chapter 3 tables where they apply to the same routes.
- "2000 S-Q" shows costs projected for the year 2000, presuming the status quo (that is, no substantial adjustment to current transportation policy).
- "2000 D" projects costs for the year 2000, presuming that the recommendations in this report, *Directions*, are implemented.

Within each block, we identify two groups that pay the costs of transportation: users and others. "Users" include travellers and carriers.

"Others" are taxpayers and those affected by such factors as environmental pollution. The three columns in the block show costs paid by users and others and the total costs.

| ***Users*** | ***Others*** |
|---|---|
| **Travellers** | **Taxpayers, through direct subsidies to carriers and subsidies for infrastructure** |
| **Carriers** | **General public, through the effects of environmental damage** |
| **Vehicle owners** | **Taxpayers, through health care costs of accident victims** |
| | **Travellers on other routes (cross subsidy)** |

**Users' Costs + Others' Costs = Total Costs**

If our recommendations changed how Canadians pay for passenger transportation, but did not change governments' or carriers' behaviour in providing transportation, or travellers' use of transportation, the impact would be simply to shift costs from others to travellers, with no impact on total costs.

In other words, total costs in the 2000 D case would be identical to the 2000 S-Q case, but others' costs in the 2000 D case would have dropped to zero (or close to zero, subject to some remaining transitional subsidies), while users' costs would have increased by a corresponding amount.

In fact, we expect that our recommendations will lead to changes in the behaviour of governments, carriers and travellers; changes that will reduce the total costs of providing transportation services. Therefore, we expect several components of the total costs in the 2000 D case to be lower than in the 2000 S-Q case, and costs to users will not, in general, have to rise by the full amount of the reduction in costs borne by others. Inevitably, our estimates of these reductions are often quite approximate; they are intended to indicate the order of magnitude of the potential for cost reductions that might reasonably be achieved when our recommendations are implemented.

The tables show cost component estimates to the nearest dollar, although in many cases the figures are subject to margins of uncertainty of several dollars or, in some cases, several tens of dollars. We trust readers will bear with us when we refer to, for example, a cost of $378, and will interpret this as roughly $400. Our use of nearest-dollar figures is motivated by our wish to show some cost components that are only a few dollars, coupled with our wish to allow readers to see how the figures in the tables add up — which would be obscured by use of rounded components and totals.

Charts 18-1 to 18-4, corresponding to the tables, provide an alternative display of the 2000 S-Q and 2000 D cases (see explanation of chart format in Chapter 3).

All four routes share common features, and we discuss these in the text for the first route, Saskatoon to Halifax.

## ROUTE #1: SASKATOON TO HALIFAX

### Saskatoon to Halifax: 1991 Costs

The average overall costs per person travelling this type of route are $747 by car, $313 by bus, $443 by airplane and $1,532 by train.

For car travel, travellers pay $168 in accident costs (through insurance premiums and uncompensated damage losses), $53 in special taxes and fees, and $487 for vehicle/carrier expenses. Of others' costs, governments pay $67 to provide infrastructure. The public bears the environmental damage costs, estimated at $19 in winter and $24 in summer, or an average of $21 year-round. Another $4 for health care costs is unrecovered from motor-vehicle insurance companies and is paid by governments, but they receive $53 in special taxes and licence fees from motorists. In aggregate, travellers pay $708, while others pay $39 per car traveller for a route of this type.

Table 18-1

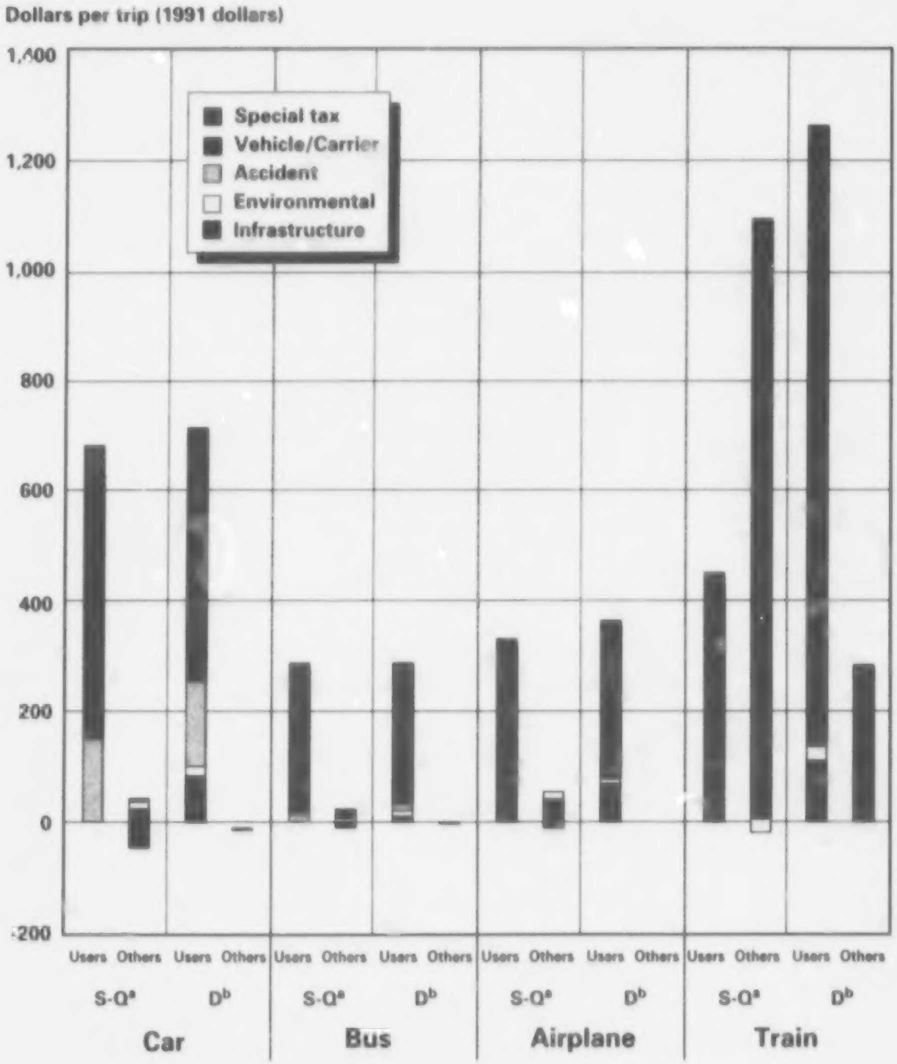
**a. It is assumed that passengers would abandon some of this rail service before 2000, as subsidies were gradually withdrawn.**

**Note: In order to illustrate smaller components, route totals are shown to the nearest dollar. In general, cost estimates are not accurate to this level of precision. See text for qualifications.**

*Chart 18-1*

ILLUSTRATIVE COMPREHENSIVE COSTS PER PASSENGER PROJECTED TO 2000, SASKATOON TO HALIFAX



a. S-Q is status quo for year 2000.
b. D is with the recommendations in "Directions" implemented in 2000.

Note: The chart is a graphic representation of Table 18-1. Any negative components of costs borne by others are represented by shifting the others bar below the zero line.[1]

By comparison, the average traveller using a public carrier pays $288 for bus, $424 for airplane and $386 for train. Others pay $25 of the costs per trip by bus, $19 per trip by airplane, and $1,146 per trip by train.

For airplanes, the vehicle/carrier cost borne by others (–$56) shows that the charges to air travellers are $56 more than the costs of providing the service. The system-average revenue for journeys of this length in southern Canada is $368 (net of taxes, infrastructure charges and traveller-borne accident costs) and the system-average cost (including normal profits) is $312. Air travellers on this route pay $56 toward the cost of other air routes. This type of route is thus currently estimated to be characterized by above-average profitability. Differences in the profitability of route types change over time. We have assumed that the average fare equals the average cost for the year 2000 in both the 2000 S-Q and the 2000 D scenarios.

### Saskatoon to Halifax: 2000 Status Quo

The estimated costs of travel in the future, without any significant change in transportation policy, allow for the following anticipated developments in traffic and technology:

- Domestic air travel and road traffic grow at 3 percent per year. We have adjusted the costs for infrastructure provided by governments to accommodate this growth.
- Considerable reductions in fuel consumption per passenger-kilometre occur as a result of new technology and the turnover of vehicle fleets — 13 percent on average for cars, and 15 percent for aircraft. Such reductions will lessen carbon dioxide ($CO_2$) emissions from these vehicles by the same proportions. Improved motor-vehicle emission control equipment reduces average emissions of nitrogen oxides ($NO_x$) and volatile organic compounds (VOCs) by 40 percent.
- New train technologies may contribute to reducing costs such as environmental damage, but we have not shown any improvement by the year 2000 given the slow turnover of long-lasting railway

locomotives. We also assume that rail passenger cars and service levels will be upgraded on the Western Transcontinental. This will be accompanied by some increase in infrastructure costs, vehicle/carrier costs, and revenues from users.

- Newer aircraft make substantially less noise; thus average noise costs fall as older models are replaced.
- Improvements in road safety continue, reducing accident costs per passenger-kilometre for car and bus by 10 percent.

Overall, total costs in 2000 S-Q fall from 1991 levels by approximately 4 percent per car trip and 15 percent per airplane trip.

### Saskatoon to Halifax: 2000 Directions

We expect important changes in all modes as a result of the implementation of our recommendations.

*Car:* The special transportation tax/fees (fuel tax and licence fees) will be replaced by specific charges for infrastructure and environmental damages. If special taxes are viewed as charges for road infrastructure, in 2000 S-Q the overall recovery of infrastructure costs from travellers is only 50 percent across the entire road network, although it amounted to $53 out of $67 on this type of route.

We expect that in the year 2000, road charges will still need to be averaged across all highways within a province or territory, although charging by route will eventually be feasible. We show the cost to users for infrastructure provided on this route as an $81 road charge in 2000 D, generating a $18 surplus over the road costs for this type of route. This is necessary to cover the deficits on more-lightly travelled highways. We expect total road costs to fall as a result of improvements in investment planning and consultation with users in the rate-setting process. This is represented by a 5 percent decrease in road infrastructure costs for car travel over the 2000 S-Q costs.

The environmental damage charge would be set at the rate for air pollutant damage, most probably as a fuel surcharge. We expect that this charge, together with the increase in fuel charges described in the preceding paragraph, will stimulate travellers to reduce fuel consumption and emissions. The result is represented by a 10 percent reduction in fuel use, and thus in environmental damage and in the fuel component of vehicle/carrier costs. The environmental damage charge to travellers is $15 per trip in winter and $18 in summer, or $16 averaged over the year.

Users pay $39 more than the 2000 S-Q costs, or a 6 percent increase. Others do not pay anything, and the $18 surplus pays for less-used highways in the provinces through which the route passes. In total, the combined costs of car travel will fall by about 2 percent from 2000 S-Q to $701 for this type of trip.

*Bus:* Bus companies, and hence bus travellers, currently and in 2000 S-Q, pay special transportation taxes/fees that, on average, more than meet the costs of the roads; thus the infrastructure charge would not differ appreciably from the current fuel tax ($9). The environmental charge to users would be $5 per trip, resulting in a slight increase per passenger in the total of infrastructure charges, environmental charges, accident costs and special taxes (with the latter having disappeared in the 2000 D scenario).

With our recommendations in place, however, the bus industry would be open to competition, giving bus companies greater commercial freedom and eliminating cross subsidization of low-volume services from higher-volume routes. The resulting improved efficiency is represented by reductions of 10 percent per passenger in vehicle/carrier costs (from $280 in the 2000 S-Q case to $252 in the 2000 D case).

The 2000 D case shows a decline of $4, or 1 percent, in total users costs; the savings induced by greater competition would, in this case, be substantially offset by the elimination of cross subsidy.

*Airplane:* Under our recommendations, the federal government will transfer the costs of airports and the air navigation system from taxpayers to travellers. In addition, most airports and the air navigation system would be run as commercial operations. For a Saskatoon–Toronto–Halifax routing, we expect such changes would reduce total air infrastructure costs from $84 per trip in 2000 S-Q to $66 per trip in 2000 D. These costs would be paid directly or indirectly by air travellers.

The environmental charge to users would be $17 per user per trip in 2000 D; at the same time, governments will eliminate special fuel taxes. The net increase or charges, in turn, would cause carriers to slightly reduce fuel consumption.

Overall, fares (total costs to users) would rise by 10 percent, or $33, reflecting the transfer of costs from the taxpayer to the traveller, but total air trip costs would fall by 5 percent.

*Train:* We are recommending that taxpayers provide passenger rail with declining subsides during a 10-year transition period. Much of the rail route between Saskatoon and Halifax is lightly used, and there are few prospects for substantial reduction in costs. For the year 2000, we show the subsidy as three-quarters phased out. The price to potential train travellers on this route, assuming no change in the number of passengers, would have risen substantially — to more than three times the average price of air travel. It seems likely that the number of travellers choosing the train would decline on several of the links that make up this route, and that passenger rail service, on some of these links, would be discontinued prior to 2000.

## ROUTE #2: TORONTO TO MONTREAL

### Toronto to Montreal: 1991 Costs

Total costs per passenger-trip on routes of the Toronto to Montreal type are $89 by car, $37 by bus, $194 by airplane and $137 by train.

On this type of route, bus passengers do not impose costs on others. The road-infrastructure costs and environmental costs are approximately balanced by special transportation taxes/fees (primarily fuel taxes). As well, fares paid by bus travellers exceed carrier costs; the excess is available to cross subsidize other bus services.

For the remaining types of travel:

- Others pay $4 of the total cost per car trip, because special taxes do not fully cover infrastructure, environmental and accident costs.
- On airplane flights, taxpayers and the public contribute a $20 shortfall in cost recovery on government-provided infrastructure plus $6 in environmental costs, minus $3 received from special (fuel) taxes. Travellers on other air routes provide $35 in estimated cross subsidy toward vehicle/carrier costs. (Travellers on this route make a lower than average contribution to overhead.)[2] Thus, in total, others contribute $58 per trip by airplane.
- Others pay $84 of the costs per passenger of the train service, nearly all for the direct subsidy to VIA Rail's vehicle/carrier costs.

### Toronto to Montreal: 2000 Status Quo

Costs per bus trip are projected to remain constant, while costs in the other modes would decrease slightly. We expect important improvements in train travel through cost economies, service improvements and revenue enhancement, so that overall cost recovery from train travellers on this route would increase from 39 percent in 1991 to 47 percent by 2000.

*Table 18-2*

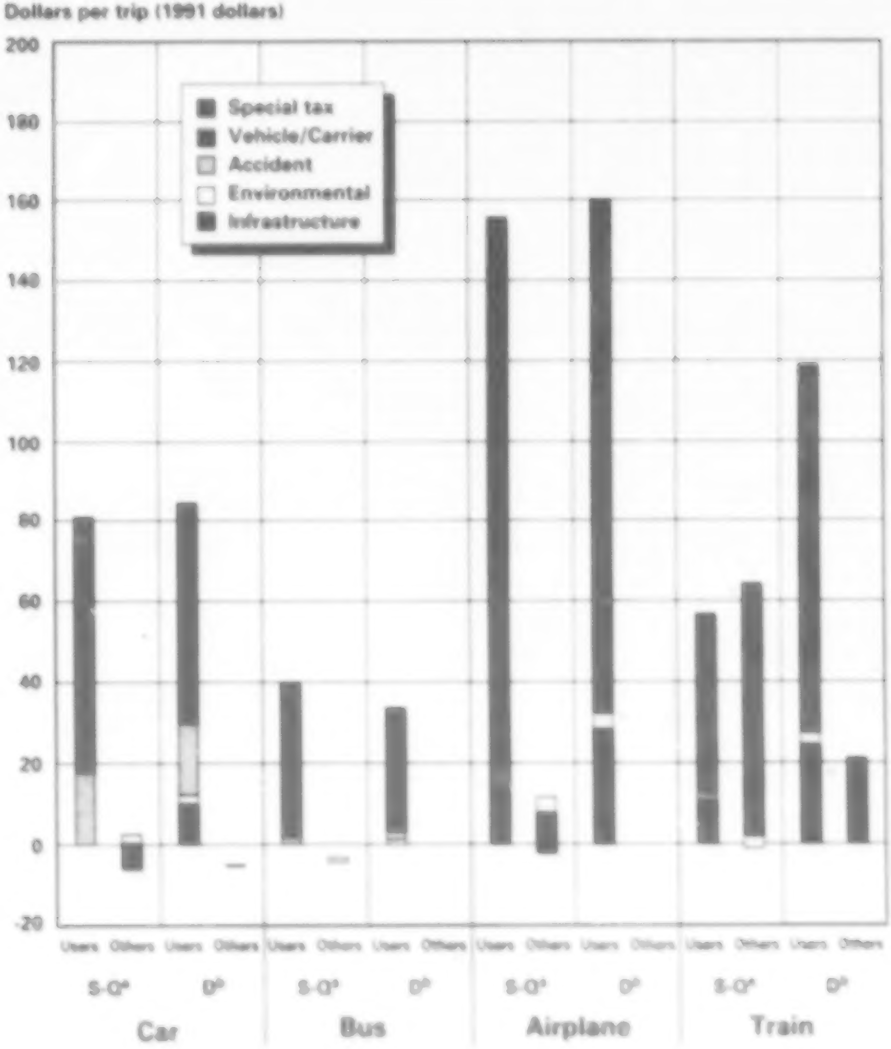
*Chart 18-2*

ILLUSTRATIVE COMPREHENSIVE COSTS PER PASSENGER, PROJECTED TO 2000, TORONTO TO MONTREAL



a. S-Q is status quo for year 2000.
b. D is with the recommendations in "Directions" implemented in 2000.

Note: The chart is a graphic representation of Table 18-2. Any negative components of costs borne by others are represented by shifting the others bar below the zero line.

**Toronto to Montreal: 2000 Directions**

*Car:* With our recommendations in place, overall costs, including environmental damage and accident costs, would fall slightly. Infrastructure charges and environmental damage charges would amount to $14 per traveller, or an increase of $8 on average per traveller over the equivalent charges (the special tax of $6) in 2000 S-Q. If this increase were charged entirely as a fuel tax, it would amount to 25 cents per litre of gasoline at current fuel consumption rates (our estimates of costs per traveller assume an average of 1.8 travellers per car).

*Bus:* As a result of deregulation and the elimination of cross subsidization through fares, total costs to users would fall by 15 percent from 2000 S-Q, becoming $34 per trip.

*Airplane:* More economical operation of airports and the air navigation system between the 2000 S-Q and 2000 D scenarios would reduce infrastructure costs by 18 percent. Eliminating the $10 subsidy from others for airport and air navigation infrastructure in 2000 S-Q would then require only a $4 increase in infrastructure charges, to $28, in 2000 D. The environmental charge of $4 compares with $3 in special taxes to users in the 2000 S-Q scenario.

*Train:* Cost recovery in 2000 S-Q would still be only about half of that required for viability, and in 2000 D, train vehicle/carrier subsidies would have decreased over a transition period. We believe, however, that there is a potential for train travel to succeed with our recommendations in place. Improved speed, comfort and service are possible on this route. Train travel could become attractive even at much higher fares. Total infrastructure and vehicle/carrier costs would increase 15 percent to $136 per trip ($25 + $111), but there would also be an increase in total revenues per user from $57 to $119. The 2000 D fare would still be $41 less than the air fare ($160 – $119). The taxpayer vehicle/carrier subsidy, which would not be completely phased out by 2000, would cover the difference of about $21 per trip.

## ROUTE #3: CHURCHILL TO WINNIPEG

### Churchill to Winnipeg: 1991 Costs

This remote route is of interest because it includes a substantial community that cannot be reached by car. Travellers from Churchill must use an airplane or train to reach Winnipeg. The costs of these modes today are:

*Airplane:* Users pay a total of $262 in air fare, while others pay $280 for the costs of the air infrastructure, particularly the Churchill airport. The total cost by air is $530 per trip.

*Train:* Users pay $229 in fares. The taxpayer contributes $2,749 per passenger to the trip — more than ten times as much as is paid by the traveller — and the total cost is almost $3,000 per passenger.

### Churchill to Winnipeg: 2000 Status Quo

Projected growth in air traffic for 2000 S-Q would reduce the cost of the airport and the air navigation system, when averaged over more passengers, but the total infrastructure cost would still be $217 per passenger. We do not foresee any decrease in costs or increase in revenues for rail service.

### Churchill to Winnipeg: 2000 Directions

For the 2000 D model, our assumptions for this type of route are as follows:

*Airplane:* Based on costs at similar non-Transport Canada airports, we believe that scaling the Churchill airport down to a size adequate to handle forecast demand, anu allowing management to pursue efficiency, would reduce the total air infrastructure costs. The historical capital costs associated with the larger airport would not determine pricing during the transition. Rather, pricing would cover new capital spending to maintain the smaller airport. The reduced infrastructure costs would still be high compared with system-average airport costs,

*Table 18-3*

## Illustrative Comprehensive Costs per Passenger in 1991, 2000 "Status Quo" and 2000 "Directions" — Route #3, Churchill to Winnipeg

| Dollars per trip, in 1991 dollars | | | | | | | | | |

| **Total** | | | | | | | **139** | **40** | **179** |

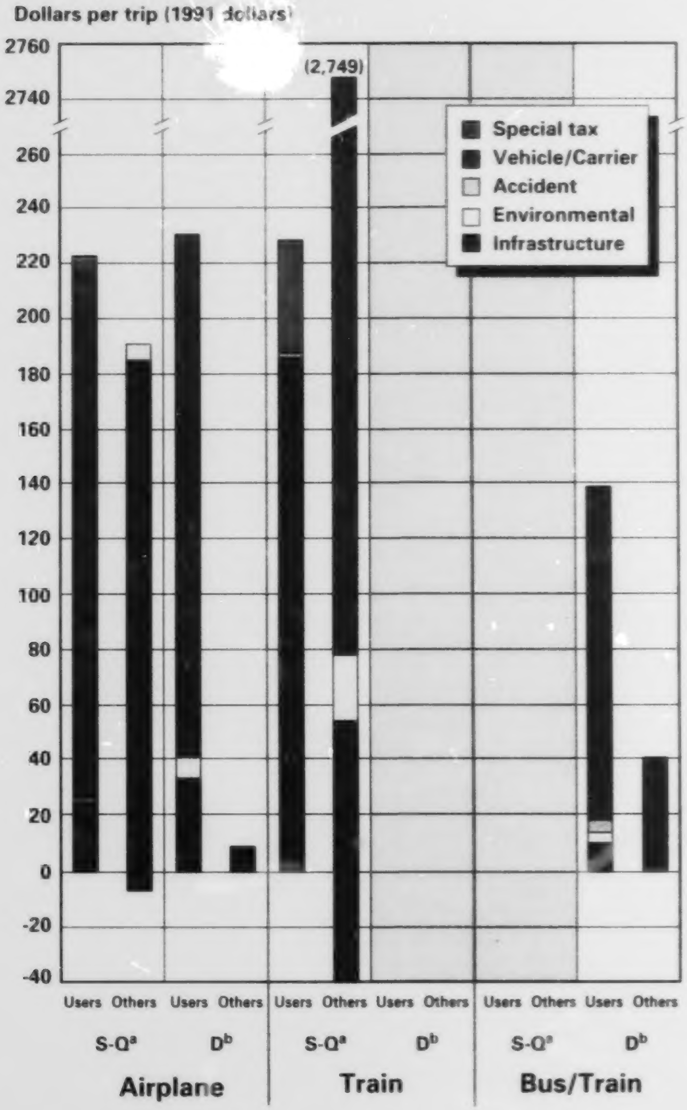
a. It is reasonable to predict that this rail service would be discontinued before 2000.

b. The bus–train service is shown as an alternative to air travel, presuming the through train service was discontinued.

Note: In order to illustrate smaller components, route totals are shown to the nearest dollar. In general, cost estimates are not accurate to this level of precision. See text for qualifications.

Chart 18-3

ILLUSTRATIVE COMPREHENSIVE COSTS PER PASSENGER, PROJECTED TO 2000, CHURCHILL TO WINNIPEG



a. S-Q is status quo for year 2000.

b. D is with the recommendations in "Directions" implemented in 2000.

Note: The chart is a graphic representation of Table 18-3. Any negative components of costs borne by others are represented by shifting the others bar below the zero line.[1]

but a major improvement over those shown in 2000 S-Q. Charging this amount to air travellers would constitute a steep increase in infrastructure charges to users (Recommendation 5.2) and result in a (decreasing) transitional subsidy from others, illustrated by the $9 shown in the table. Total infrastructure costs would be $43. The total fare paid by air travellers would rise from $223 in 2000 S-Q to $231.

*Train:* Since train service will never approach self-sufficiency on this route, we predict that the current service would be discontinued before 2000; we therefore show no figures for standard rail service in 2000 D. We searched for an alternative that passengers could afford and that did not impose such large costs on the taxpayer. Passengers from smaller communities along the rail line from Gillam to Churchill can be reliably served only by the train; the airplane-only option is restricted to residents of Churchill itself. We therefore developed a model for a bus-train intermodal system that would be effective and reasonably priced.

*Bus-Train:* There is bus service from Winnipeg to Gillam, 265 kilometres south of Churchill. This bus service combined with a mixed train (offering coach and freight services) would provide transportation to Churchill. Although the train segment of this bus-train service would lack the comforts of the present sleeper service (meal and beverage amenities), the distance and time involved would be much less. Such a service could achieve, or come much closer to achieving, full cost recovery. It is another example of when a transitional subsidy would be warranted. This is represented by a $40 others' contribution to vehicle/carrier costs. The subsidy would be payable on the Gillam to Churchill segment of the route. The total cost would be $179 per passenger.

*Other alternatives:* The very small population that lives along the rail line from Gillam to Churchill could also be served from Winnipeg by air to Gillam or Churchill and by the revised train service discussed earlier.

## ROUTE #4: HALIFAX TO ST. JOHN'S

This route involves crossing between Nova Scotia and Newfoundland by air or by one of the two ferries: the year-round service between North Sydney, Nova Scotia, and Port aux Basques, Newfoundland, or the summer service between North Sydney, Nova Scotia, and Argentia, Newfoundland.

The combined road and ferry distances differ greatly between these two routes.

- Using the Port aux Basques ferry, the crossing is 178 kilometres and the road trip is 1,267 kilometres, for a total trip of 1,445 kilometres.
- Using the Argentia ferry, the crossing, which is 519 kilometres, reduces the road trip by 798 kilometres to 469 kilometres, for a total trip length of 988 kilometres.

With the exception of Halifax to Truro, no passenger rail services exist between Halifax and St. John's. The alternative means from Halifax to St. John's are airplane, bus-ferry or car-ferry. Table 18-4 illustrates five route combinations, including bus and car, using each of the two ferry routes.

### Halifax to St. John's: 1991 Costs

Overall total costs per passenger-trip are:

- $214 by airplane;
- $333 by car-ferry using the Port aux Basques ferry;
- $292 by car-ferry using the Argentia ferry;
- $181 by bus-ferry using the Port aux Basques ferry; and
- $150 by bus-ferry using the Argentia ferry.

a. Port aux Basques.

Note: In order to illustrate smaller components, route totals are shown to the nearest dollar. In general, cost estimates are not accurate to this level of precision. See text for qualifications.

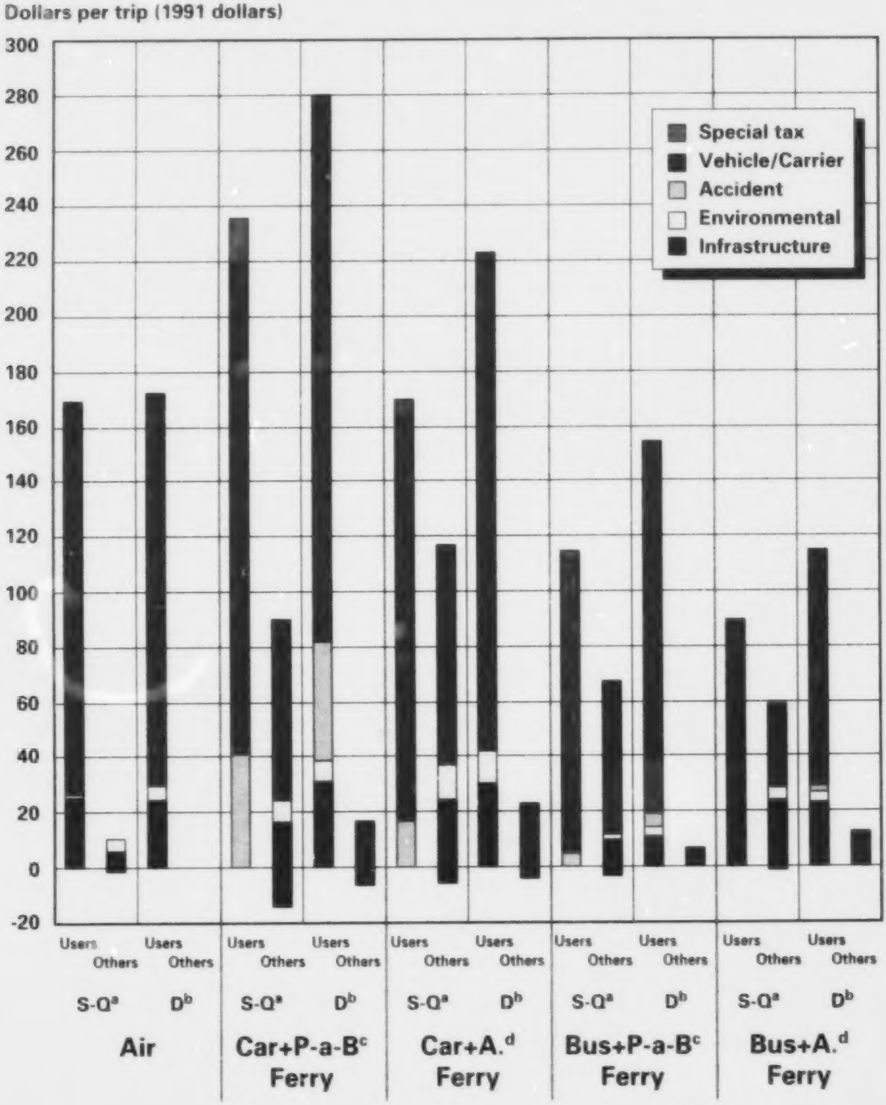
In more detail, they are:

*Airplane:* Users pay an average fare of $184 for this type of route. Taxpayers pay $21 for unrecovered airport and air navigation infrastructure costs, and the public bears $6 in environmental damage. One dollar is recovered in fuel tax, and air passengers on other routes pay $4 in a cross subsidy to vehicle/carrier costs. The total contributed by others is $30 per passenger.

*Car-ferry using the Port aux Basques ferry:* (For this and the following three trips, the text reports some costs for the modal segments that are not shown in the table.) Average costs per traveller for the road

Chart 18-4

## ILLUSTRATIVE COMPREHENSIVE COSTS PER PASSENGER, PROJECTED TO 2000, HALIFAX TO ST. JOHN'S



a. S-Q is status quo for year 2000.
b. D is with the recommendations in "Directions" implemented in 2000.
c. Port aux Basques.
d. Argentia.

Note: The chart is a graphic representation of Table 18-4. Any negative components of costs borne by others are represented by shifting the others bar below the zero line.[1]

segments of the trip are $213, of which $13 is borne by others in unrecovered infrastructure and environmental damage costs.

Others contribute considerably to the ferry portion of the trip. While a user pays $44 for the ferry, federal taxpayers contribute an estimated $8 for such infrastructure as coast guard and navigation aids on this route. In addition, the direct vehicle/carrier subsidy to the carrier from federal taxpayers is $64 per car traveller. Combining the car and ferry costs, travellers pay a total of $244 and others pay $89.

*Car-ferry using the Argentia ferry:* Costs for the road portions of the trip are $78; travellers pay all but $4. Of total ferry costs of $214, travellers pay $100 and others pay $80 in direct subsidy. In addition, others pay $24 in infrastructure costs and $10 in environmental damage for the ferry crossing. In combination, travellers pay $174 and others pay $118 of the total cost of $292 per passenger.

The Argentia route is advantageous to travellers to St. John's. It costs less than the Port aux Basques route when all car costs are included and eliminates 800 kilometres of driving. This route, however, costs the taxpayer more than the Port aux Basques route with current pricing and subsidy policies. Travellers currently pay less on the Argentia ferry route than if they were travelling by airplane, although the full costs per passenger for the trip are much lower by airplane.

*Bus-ferry using the Port aux Basques ferry:* To use this route, travellers must take a bus in Nova Scotia operated by a private carrier and cross Newfoundland on the Crown-owned CN Roadcruiser bus. Although we estimated the average fares from actual 1992 full-fare figures, the bus costs in the table are not those of any of the carriers involved but generic costs estimated from data for a number of carriers. Our table reflects a $33 vehicle/carrier subsidy from passengers on other routes and from bus carrier losses (borne by shareholders, which in CN's case is the federal government) and an estimated total bus fare of $99. The traveller pays $15 of the ferry service.

Taxpayers contribute $8 to marine infrastructure costs and pay a vehicle/carrier subsidy of $22. Including all components, total ferry costs are $46.

Combined fares for the bus and ferry portions of the trip are $114 paid by passengers, toward a total cost of $181 per passenger.

*Bus-ferry using the Argentia ferry:* Travellers also require bus service in Nova Scotia and Newfoundland for this trip. Both bus services are run by privately owned carriers; the Newfoundland run is much shorter than that required for travellers using the Port aux Basques ferry. The combined bus carriers' costs are estimated at $42 per trip, while the average bus traveller pays $45 in fares. Bus carriers use the extra $3 to cross subsidize passengers on other routes.

The traveller pays $42 in ferry costs. Taxpayers contribute $24 for marine infrastructure, and $34 in vehicle/carrier subsidies, for a total of $58. Together with environmental damage costs, total ferry costs are $106.

The combined fare for the bus and ferry portions of this trip is $91, while the total cost is $150.

### Halifax to St. John's: 2000 Status Quo

Air infrastructure costs per passenger would fall as traffic increased at a greater rate than spending on airports and air navigation services. Airplane and car costs would also decline slightly as fuel consumption and emissions decreased and road accident costs fell. Costs of the bus and ferry services would remain the same.

### Halifax to St. John's: 2000 Directions

When our recommendations are implemented, we expect the following changes in costs by mode:

*Airplane:* Airport and air navigation spending (infrastructure) would fall by 25 percent to $24 per passenger for this trip. Travellers would pay all costs, including charges for infrastructure and environmental damage. Total costs per passenger would decline to $171. The total costs in the 2000 D case are expected to be almost the same as the traveller costs in the 2000 S-Q case.

*Car:* Car costs would change in the same proportions as those on the other routes. Road infrastructure costs would fall because only part of the growth in traffic would be met by increases in capital and operating spending. This is represented as a 5 percent decrease in infrastructure costs. The fuel tax would be changed into a road infrastructure charge and would almost double in order to cover costs throughout the road network. This increase, plus the charge to travellers for environmental damage, would bring a 10 percent reduction in environmental damage costs and the fuel component of vehicle/carrier costs.

*Bus:* Deregulation would encourage efficiency in operations and remove cross subsidization. Privatization or contracting for operation of the government-owned Newfoundland service could also result in cost reductions.

*Ferry:* With full cost recovery for navigation services and with transparency of cost-related decisions, we expect total costs for water infrastructure to fall 10 percent. The federal government would ensure full cost recovery in ferry financing by decreasing vehicle/carrier subsidies over the next 10 years. By 2000, subsidies would be only 25 percent of their 1991 levels, with elimination of remaining amounts scheduled for 2002 if that were consistent with continuing to meet Constitutional obligations to ensure service. Management would be directed to focus on efficiency. As a result, we expect ferry costs to fall 20 percent. Further, ferry users would not be charged with any extra costs associated with requirements to construct vessels in domestic shipyards.

In summary, under our recommendations the overall costs of the air, car-ferry and bus-ferry services would decrease notably. Most of the others costs would be paid by travellers. Total users' charges would therefore increase relative to the 2000 S-Q case from:

- $168 to $171 for airplane;
- $236 to $280 for car-ferry costs on the Port aux Basques route;
- $170 to $224 for car-ferry costs on the Argentia route;
- $114 to $154 for bus-ferry costs on the Port aux Basques route; and
- $91 to $116 for bus-ferry costs on the Argentia route.

## TOTAL SYSTEM COSTS

Illustrating the effects of our recommendations on the four routes gives some idea of the way we expect our recommendations to affect travellers using different routes and modes. To understand how our recommendations would affect the economy and taxpayers in general, it is also necessary to attempt to approximate the total effects.

We have done this using three tables:

*Table 18-5:* Total costs for Canada's intercity passenger transportation system projected to the year 2000, presuming no substantial adjustment in current transportation policy (the 2000 S-Q case). The table includes the costs for each means of travel and for total intercity travel.

*Table 18-6:* Total costs projected to the year 2000 after governments implement our recommendations (the 2000 D case). The table includes the costs for each means and for total intercity travel.

*Table 18-7:* Shows the 2000 D costs less the 2000 S-Q costs; this is an indication of the impact of the recommendations on the costs for each means of travel and for total intercity travel.

The tables are set up in a similar fashion to those for the illustrative routes. For the different components of transportation costs (infrastructure, environmental, accident, special taxes/fees and vehicle/carrier), the first and second columns indicate who pays — users and others including both the taxpayers and the public. The third column is the sum of the first two. The amounts in all tables are in 1991 dollars.

## TOTAL COSTS IN THE 2000 STATUS-QUO CASE: TABLE 18-5

We based our calculations on simple projections of traffic growth from 1991 to 2000, consistent with those for the illustrative routes. For example:

- car and airplane travel will grow by 30 percent;[3]
- ferry travel will grow by 30 percent;[4] and
- bus and train travel will not change.[5]

As with the illustrative routes, we calculated total system costs to reflect the expectation that the average cost per passenger-kilometre will fall by the year 2000 due to trends in technology and traffic growth. For example (all references are per passenger-kilometre):

- fuel consumption will decrease by 13 percent for cars and 15 percent for airplanes;
- environmental damage from cars will drop by 20 percent, and from airplanes by 25 percent;
- accident costs for cars and buses will fall 10 percent;
- carrier operating costs for trains will be reduced by 5 percent;
- average costs of airport and air navigation infrastructure will decrease as use of the existing capacity grows; and
- ferry costs remain unchanged for the individual services, but the average declines slightly due to the faster growth in traffic on the lower cost services.

The result of these changes will be that total costs per passenger-kilometre fall by 3 percent for travel by car, 4 percent for train, 15 percent for airplane, 3 percent for ferry and remain unchanged for bus. Of course, with increases in traffic, the total amount spent on domestic passenger transportation will rise substantially between 1991 and 2000.

*Table 18-5*

## TOTAL COSTS WITH OUR RECOMMENDATIONS IMPLEMENTED: TABLES 18-6 AND 18-7

The passenger transportation system would be fairer for all Canadians after our recommendations are implemented. Travellers would pay all the costs of their travel, including the costs of the damage they cause to the environment and of accidents. The result would be that most travellers would pay more for travel but this would be more than balanced by the reductions in what general taxpayers and the public would pay to support the passenger transportation system, reflecting a reduction in total costs — including environmental costs.

Putting our recommendations in place would cause changes in amounts of travel, varying by the means of transportation. With the increase in car and air costs to travellers, some reduction in use of these means is expected. With the increase in the price to the traveller of car and air travel, and reduction in price and improvement in service of main-route bus travel, some increase in use of the bus is expected. With only small percentage shifts from car and airplane to bus, more than a doubling in the use of intercity bus is entirely possible. Some increase in train travel on the remaining routes may be achieved through better service, in spite of the increase in fares. Ferry travel will tend to be reduced by higher fares, although it is not likely to be very responsive to price.

It is easier, however, to make and interpret cost comparisons under the assumption that traffic patterns and levels do not change from the 2000 S-Q to the 2000 D case. The figures in tables 18-6 and 18-7 for the different means of transportation are calculated using this assumption, with the exception that total train passenger-kilometres are reduced by 50 percent, reflecting our prediction that a number of passenger rail services would cease to operate as the subsidy is reduced. These figures are used in discussing changes in costs for the individual means of travel.

Table 18-6

### ILLUSTRATIVE SYSTEM-WIDE ANNUAL COSTS OF INTERCITY DOMESTIC TRAVEL IN 2000 "DIRECTIONS"

**Totals: $ millions, in 1991 dollars**

| Type of cost | Car (270 billion pass-km) | | | Bus (3.3 billion pass-km) | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 5,491 | 0 | 5,491 | 9 | 0 | 9 |
| Environmental | 1,122 | 0 | 1,122 | 6 | 0 | 6 |
| Accident | 9,414 | 0 | 9,414 | 12 | 0 | 12 |
| Special trans. tax/fee | 0 | 0 | 0 | 0 | 0 | 0 |
| Vehicle/Carrier | 28,480 | 0 | 28,480 | 237 | 5 | 242 |
| **Total** | **44,507** | **0** | **44,507** | **264** | **5** | **269** |

| Type of cost | Airplane (33 billion pass-km) | | | Train (1.4 billion pass-km) | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 1,133 | 40 | 1,173 | 32 | 0 | 32 |
| Environmental | 253 | 0 | 253 | 4 | 0 | 4 |
| Accident | 33 | 0 | 33 | 1 | 0 | 1 |
| Special trans. tax/fee | 0 | 0 | 0 | 0 | 0 | 0 |
| Vehicle/Carrier | 4,127 | 0 | 4,127 | 181 | 60 | 241 |
| **Total** | **5,546** | **40** | **5,586** | **218** | **60** | **278** |

| Type of cost | Ferry (1.1 billion pass-km) | | | All intercity travel (310 billion pass-km) | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | **Users** | **Others** | **Total** |
| Infrastructure | 47 | 0 | 47 | **6,725** | **40** | **6,765** |
| Environmental | 17 | 0 | 17 | **1,405** | **0** | **1,405** |
| Accident | 1 | 0 | 1 | **9,470** | **0** | **9,470** |
| Special trans. tax/fee | 0 | 0 | 0 | **0** | **0** | **0** |
| Vehicle/Carrier | 320 | 28 | 348 | **33,411** | **93** | **33,504** |
| **Total** | **385** | **28** | **413** | **51,011** | **133** | **51,144** |

Note: **In order to illustrate smaller components, figures are shown to the nearest $ million. In general, cost estimates are not accurate to this level of precision. See text.**

**Costs for means of travel do not sum to costs for all intercity travel, as the latter also includes allowance for costs of increased car, bus and airplane travel to replace assumed reduction in rail travel between 2000 S-Q and 2000 D cases. See text.**

## Table 18-7

## ILLUSTRATIVE SYSTEM-WIDE ANNUAL COSTS OF INTERCITY DOMESTIC TRAVEL, CHANGES BROUGHT BY IMPLEMENTING "DIRECTIONS" COMPARED WITH THE "STATUS QUO"

**Totals: $ millions, in 1991 dollars**

| Type of cost | Car | | | Bus | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 5,491 | -5,769 | -278 | 9 | -10 | -1 |
| Environmental | 1,122 | -1,247 | -125 | 6 | -8 | -2 |
| Accident | 201 | -202 | -1 | 0 | 0 | 0 |
| Special trans. tax/fee | -3,199 | 3,199 | 0 | -9 | 9 | 0 |
| Vehicle/Carrier | -474 | 0 | -474 | -40 | -3 | -43 |
| **Total** | **3,141** | **-4,019** | **-878** | **-34** | **-12** | **-46** |

| Type of cost | Airplane | | | Train | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 410 | -661 | -251 | -13 | 0 | -13 |
| Environmental | 253 | -266 | -13 | 4 | -9 | -5 |
| Accident | 0 | 0 | 0 | -2 | 0 | -2 |
| Special trans. tax/fee | -165 | 165 | 0 | -6 | 6 | 0 |
| Vehicle/Carrier | 0 | 0 | 0 | 82 | -375 | -293 |
| **Total** | **498** | **-762** | **-264** | **65** | **-378** | **-313** |

| Type of cost | Ferry | | | All intercity travel | | |
|---|---|---|---|---|---|---|
| | Users | Others | Total | Users | Others | Total |
| Infrastructure | 47 | -52 | -5 | 5,957 | -6,492 | -535 |
| Environmental | 17 | -22 | -5 | 1,405 | -1,552 | -147 |
| Accident | 0 | 0 | 0 | 208 | -202 | 6 |
| Special trans. tax/fee | -10 | 10 | 0 | -3,389 | 3,389 | 0 |
| Vehicle/Carrier | 56 | -85 | -29 | -310 | -463 | -773 |
| **Total** | **110** | **-149** | **-39** | **3,871** | **-5,320** | **-1,449** |

Note: In order to illustrate smaller components, figures are shown to the nearest $ million. In general, cost estimates are not accurate to this level of precision. See text.

Costs for means of travel do not sum to costs for all intercity travel, as the latter also includes allowance for costs of increased car, bus and airplane travel to replace assumed reduction in rail travel between 2000 S-Q and 2000 D cases. See text.

It would be inappropriate to compare total passenger transportation costs for all means of travel in the 2000 S-Q and the 2000 D cases on this basis, because no allowance is made for replacement of the reduced train travel. Thus the estimates for costs of all intercity travel in tables 18-6 and 18-7 are calculated using the illustrative assumption that the entire reduction in rail travel shifts to other means: car, bus and airplane travel are each increased by one third of the reduction in train passenger-kilometres.

### Car Travel

Drivers and owners will pay the full costs of travelling by car. The results:

- *Infrastructure:* Charges to users would be about $5.5 billion, replacing the special transportation taxes/fees, which we estimate at $3.2 billion for 2000 S-Q. This increase is the amount we expect (by our rough calculations) to be needed in the long term to recover all of the costs of building and maintaining roads, including the costs of land and an interest charge on capital. In addition, the total costs of roads will fall by about 5 percent ($278 million), relative to the 2000 S-Q case. In 2000 S-Q, we assumed that road infrastructure expenditures would be increased in proportion to traffic, but in the 2000 D case — where more careful scrutiny of the benefits and costs of expenditures would be given in improving and extending the highway network — we assume that expenditures will need to increase less than proportionately to traffic growth over this period.

Once our entire framework is in place, with investment decisions and pricing designed as we suggest, the annual revenues would, on average, equal the annual costs. In particular years, however, there might be substantial cash surpluses or cash requirements due to the irregularity of road construction. During early years, our proposed pricing based on the annual costs of the existing highway network might generate considerable cash surpluses. Such prices, however, would be intended to provide an appropriate measure of the long-run costs of the different means of passenger transportation, and to provide the road agencies with information on which to base investment decisions. Interim surpluses, not required for long-term network expansion, would represent a return to governments on past investment.

- *Environmental costs:* Car users will pay about $1.1 billion for the damage they cause to the environment. Emissions will decline due to decreasing fuel consumption, and environmental costs will fall by 10 percent ($125 million).
- *Accident costs:* Car users will pay directly for that portion of total accident costs previously borne by taxpayers through general taxes and/or health care premiums.
- *Vehicle/carrier costs:* These costs will fall by about 1.5 percent ($474 million) due to the reduction in fuel consumption.

The overall result of the implementation of our recommendations for car travel is as follows:

- users' costs will rise by $3.1 billion, or 8 percent;
- others will save $125 million because total environmental costs will decline by 10 percent, and about $1.1 billion which users will pay in environmental charges. Governments could use a part of the $1.1 billion for environmental clean-up and compensation, and the remainder (probably the larger part) to reduce general taxes. Others will also save $2.8 billion in previously hidden net subsidies (the excess of subsidies to infrastructure and accidents over special taxes); and
- total car costs will fall by $0.9 billion, or 2 percent.

It would be a natural extension to apply some or all aspects of the approach that we recommend for car travellers using highways, to cars using urban streets and secondary rural roads, and to trucks. The changes in costs for all users of all roads would be substantially larger than the changes discussed above.

**Bus Travel**

Competition among bus companies and discontinuation of cross-subsidized services on local routes where demand is insufficient to cover costs is projected to reduce carrier costs by 15 percent per passenger-kilometre.[6]

- *Infrastructure costs:* Charges to buses for use of roads are projected to be only slightly higher than the present special fuel tax. Per passenger-kilometre, costs should fall as average load factors improve.
- *Environmental costs:* These costs, and the charges to bus carriers, will amount to $6 million, or approximately 2 percent of total cost.

These increases in charges to bus travellers will be more than offset by decreases in bus carrier costs and therefore:

- bus traveller fares, which would now cover all infrastructure and environmental costs, will fall by 11 percent; and
- the total amount paid by others ($17 million) in 2000 S-Q will be reduced by $12 million, to $5 million in direct (transitional) subsidies.

**Airplane Travel**

Air carrier costs will remain the same, while changes in the operations of airports and air navigation services will stimulate innovation and efficiency. The costs of air travel are projected to change as follows:

- *Infrastructure costs:* Charges for airports and air navigation services paid by travellers will increase by about $400 million, or 1.3¢ per passenger-kilometre. Others will save about $650 million at this point in the phase-out of taxpayer subsidies. An 18 percent ($251 million) reduction in total airport and air navigation costs is projected.
- *Environmental costs:* Environmental charges and improved air traffic control are projected to achieve a 5 percent reduction in

emissions. Air travellers will pay about $250 million for the damage they cause to the environment.

The results of the implementation of our recommendations are that:

- travellers will pay $500 million, or 10 percent, more for airplane travel;
- costs of $750 million net of special charges, previously borne by taxpayers in airport and navigation service subsidies and by the public in environmental damage, will be eliminated; and
- total air travel costs will fall by 5 percent, or $250 million.

**Train Travel**

The rationalization of passenger rail service will be accompanied by a reduction of direct vehicle/carrier subsidies by others of $375 million. To the extent that the 2000 S-Q subsidies of $435 million include return on investment, and that rationalization may require write-offs and special payments, annual savings may be somewhat reduced in the short run from the levels shown.

**Ferry Travel**

Governments will phase out subsidies to ferry services over a 10-year period.

- *Infrastructure costs:* Transport Canada spending will decrease by 10 percent, with full cost-recovery from travellers. New charges to users will total $47 million, or $37 million more than the special tax/fee (fuel tax) that the charges replace.

- *Environmental costs:* Environmental charges will stimulate a 20 percent reduction in ferry emissions. Travellers will pay $17 million for the damage they cause to the environment.

Direct vehicle/carrier subsidies will fall by $85 million by 2000, leaving $28 million for subsidy for operations that year. East-coast ferry services, which require more subsidies than those on the west coast, will be the most affected by the transfer of taxpayer-supported ferry costs to ferry travellers.

Our recommendations will encourage increased efficiency:

- charges to ferry travellers will rise by 40 percent ($110 million);
- savings to others will total $149 million; and
- ferry costs will fall by 9 percent ($39 million).

**Total Intercity Travel**

With our recommendations in place, there will be a transfer of costs from taxpayers to travellers using the passenger transportation system. Allowing for the replacement of the least competitive half of rail passenger-kilometres by car, bus and air travel:

- *Users:* Travellers will pay $6.0 billion per year more in infrastructure charges, $1.4 billion in environmental damage charges and $200 million in accident charges. Travellers will save $3.4 billion in special taxes (mostly fuel taxes) and more than $300 million in vehicle/carrier costs. Total net costs for travellers will therefore increase by $3.9 billion.
- *Others:* General taxpayers will save $6.5 billion per year in subsidies for transportation infrastructure (mostly roads and airports). In addition, general taxpayers will gain $1.4 billion because of charges for environmental damage, some of which may be used to compensate for environmental damage losses. The public will gain about $150 million in reduced environmental damage. Others will also save $200 million in health care for accident victims. After subtracting $3.4 billion in revenues because special taxes on travellers no longer exist, and after including $500 million saved due to discontinuing subsidies to trains and ferries, the general taxpayer/general public saves $5.3 billion.

## CONCLUSION

Our illustrative estimates in this chapter have been intended to provide:

- an impression of the extent to which the change in how Canadians pay for transportation would raise costs to Canadians when they travel — on illustrative routes and in general — at the same time that it reduces costs to Canadian taxpayers; and
- an impression of the potential for reducing overall costs as a result of implementing our recommendations.

With all our recommendations in place, there will be annual savings in most types of transportation costs that could be in the order of:

- $500 million in infrastructure costs;
- about $150 million in environmental damage costs; and
- $800 million in vehicle use and carrier costs.

Total cost of intercity passenger travel would fall by 3 percent, or $1.4 billion per year.

# ENDNOTES

1. As set out in Endnote 1 to Chapter 3, for individual routes, cross subsidies as well as special transportation taxes/fees are potential negative components of others' costs.

   When users pay more than the vehicle/carrier costs (or — in the 2000 D case — than the infrastructure costs) associated with the route used, the excess is considered a contribution from users to others (other travellers). When this occurs, the base of the others bar is shifted below the zero line by an amount equal to the sum of revenues from special taxes and fees (a negative component of others costs) and of negative cross subsidies (cross subsidies available for other travellers).

   For example, for bus travel on the Toronto to Montreal route (Table 18-2 and Chart 18-2), in the 2000 S-Q case the others bar starts at -4, the sum of -1 from special taxes and -3 from cross subsidy.

   Only the positive components of others' costs are shown as explicit segments of the bar. For Toronto to Montreal bus travel, the positive components sum to 1, which is the vertical height of the bar above its -4 base.

   In a few cases for the individual routes, the negative components exceed the positive components of costs borne by others, resulting in negative net costs. In such cases, the top of the others bar, which indicates net costs borne by others, is below the zero line. For example, again for Toronto to Montreal bus in the 2000 S-Q travel case, Table 18-2 shows net costs borne by others of -3. The top of the others bar for bus travel in Chart 18-2 S-Q thus lies below the zero line at -3.

   As well, for car travel in certain of the 2000 D cases, the only non-zero component of others' costs appears in the infrastructure row, and is negative if infrastructure users on this route are paying "extra" to cover costs of lower volume routes. In other words they are covering a cross subsidy to car travellers on lower volume routes. In such cases, the others' costs are represented by a line that lies below the zero line at the level of (negative) net others' costs on this route. For example, the -5 infrastructure costs, and net costs, for others in Table 18-2 for car travellers from Toronto to Montreal in the 2000 D case, is represented by a line in Chart 18-2 lying below the zero line at -5.

2. The $35 shortfall below average cost does not mean that the carrier would be better off dropping the service. Rather, jet operations of this length do not contribute as greatly to airline fixed costs and profits as do longer journeys. There is competition from car, bus and train, as well as from other air carriers on routes of this type. Therefore, it is not surprising that profitability might be below the system average.

3. Growth of 30 percent to the end of the decade amounts to about 3 percent annually, consistent with what is believed (in the absence of national statistics) to have occurred in total car traffic during the 1980s; and consistent also with Transport Canada's prediction for domestic air passengers to 2000.

4. The annual number of ferry passengers grew between 1980 and 1988 by 10.5 percent on the east-coast services and by 46 percent on west-coast services.

5. These types of traffic have seen inconsistent fluctuations in the last two decades. For both, passengers carried increased in the late 1970s and early 1980s. A gradual decline followed in train traffic, with a sharp reduction in traffic following the service cuts in 1990. Bus traffic has also declined substantially since 1982.

6. This system average reduction of 15 percent differs from the 10 percent reduction assumed for the higher volume intercity routes shown in Tables 18-1, 18-2 and 18-4. The latter primarily reflects assumed reduction in average operations costs per passenger on given services. The assumed system average reduction, however, is also substantially influenced by the anticipated improvement in average load factor (passenger-kilometres per available seat-kilometre) across the system as a whole. This will result from the discontinuation of cross subsidized services, and particularly from schedules and the use of equipment better matched to lower volume routes.

# CHAPTER 19

# REACHING OUR DESTINATION: A PASSENGER TRANSPORTATION FRAMEWORK FOR THE 21ST CENTURY

## INTRODUCTION

In Chapter 4, we set out the foundations for a new passenger transportation framework. These foundations included a goal and four objectives along with principles for travellers, carriers and the providers of infrastructure — terminals, links and traffic control services. We also discussed the implications for governments and the transition mechanisms needed to help travellers, carriers and infrastructure providers adjust to a new framework based on these foundations.

In Chapters 5 to 16, we made recommendations that will enable governments to bring current passenger transportation policy into line with our goal, objectives and principles.

In this chapter, we repeat our principles from Chapter 4 and summarize our recommendations with respect to each principle. This provides a comprehensive list of the changes that we recommend. These changes, when implemented into laws, regulations and institutional adjustments, will result in a new passenger transportation framework for the 21st century. We conclude with a discussion on how these changes will meet our objectives.

## ACHIEVING OUR FRAMEWORK

In this section, we restate our principles and summarize the changes that we recommend for their implementation. We do not intend this list of changes to be a menu from which to pick and choose. Our recommendations are interrelated and their positive impacts must be combined to put our framework into effect.

## Paying the Full Costs of Travel

**Each traveller will pay the full cost of his or her travel, and travellers, in total, will pay the full cost of the passenger transportation system, including those costs related to protecting the environment, safety and accidents.**

**(Recommendation 4.3)**

Taxpayers will not subsidize travellers. Rather, travellers using a public mode of transportation will pay fares sufficient to cover their share of the carrier's full cost of providing services, including the cost of terminals, links and traffic control. Similarly, private-car and private-airplane operators will pay taxes or charges sufficient to cover their share of the full cost of terminals, links and traffic control. Travellers will also pay, through either a portion of their fare, a tax or a charge, for any environmental damage they cause and for all safety and accident costs associated with their travel.

Specifically:

- Charges for environmental damage will include the costs of clean-up and mitigation, administration of policies and regulations, compensation to those affected and a best estimate of damage where compensation cannot be made.
  (Recommendation 7.4)
- Where environmental goals have been established in the absence of reliable information on damage costs, governments will set environmental charges and/or regulations at a level expected to induce the behavioural change needed to meet such goals.
  (Recommendation 7.5)

- Charges for safety and accident costs will include the cost of safety services provided by governments, and health care costs currently borne by the health insurance system.
(Recommendation 8.1)

**Access for People with Disabilities**

**Travellers with physical or mental disabilities will have opportunities similar to those enjoyed by all Canadians to use public passenger transportation.**

**(Recommendation 4.4)**

While governments and industry have taken important steps to provide access to intercity passenger transportation services for people with disabilities, our approach will go further. Carriers and providers of infrastructure will be required to take greater responsibility to provide accessible passenger transportation.

Specifically:

- Governments will establish a goal that all travellers in Canada have access to public transportation in a safe, reasonably comfortable and dignified fashion, irrespective of physical or mental ability.
(Recommendation 9.1)
- Carriers and providers of infrastructure will decide how best to meet performance standards that provide improved accessibility for people with disabilities and will do this within a reasonable period of time.
(Recommendation 9.5)
- Carriers and providers of infrastructure will begin immediately to ensure that their specifications for new equipment and infrastructure provide continuing improvements in accessibility, and will

implement, where practicable, retrofitting programs for their equipment and infrastructure.
(Recommendation 9.3)

- Groups representing people with disabilities, carrier associations and the National Transportation Agency will jointly establish a mechanism, such as a coded identification card system, that will enable carrier personnel to quickly identify the kinds of services and facilities needed by each traveller with a disability, including whether or not the traveller requires an attendant for safety or other reasons.
(Recommendation 9.6)

- When the National Transportation Agency or a carrier decides that, for safety reasons, an attendant is needed during a trip to assist an individual with a disability, the attendant's fare will be borne by the carrier.
(Recommendation 9.8)

- Carriers will ensure that any personnel who might be required to assist travellers with disabilities are trained to deal with such travellers with sensitivity and understanding.
(Recommendation 9.9)

- Canadians with disabilities, governments, carriers and manufacturers, through advisory and coordinating groups, will ensure that new services, equipment and infrastructure adequately serve those for whom they are intended.
(Recommendation 9.11)

## CHANGES FOR CARRIERS

**Competition and market forces will be the prime agents in providing viable and efficient carrier services.**

**(Recommendation 4.5)**

Carriers will provide services in a competitive environment, operating under the same commercial principles, economic forces and general rules as other businesses.

Governments will make the entry of new competitors into all carrier services easier by eliminating or easing restrictions. All potential entrants that are "fit, willing and able" will have an opportunity to supply passenger carrier services and have access to terminals, links and traffic control so long as they are prepared to pay their share of the costs, as well as any costs they impose with respect to environmental damage, safety and accidents. As well, anyone providing a carrier service will be able to withdraw these services, without undue delay, subject to adequate notice.

Specifically:

- Federal, provincial and territorial governments will amend their legislation concerning the regulation of intercity buses to reduce entry restrictions to "fit, willing and able" criteria, and require only public notice of route abandonments and publication of schedules and fares.
  (Recommendation 13.1)
- The federal government and the Government of Alberta will amend their legislation to eliminate the 10 percent ceiling on individual holdings that currently applies to Air Canada and Pacific Western Airlines, the parent of Canadian Airlines International.
  (Recommendation 11.2)
- The federal government will invite Canadian air carriers to make public proposals for future international air route designations, with the air carrier offering the best package to be granted the route and the reasons made public, and Canadian air carriers will be allowed to sell designated international routes to one another.
  (Recommendations 11.3 and 11.4)
- Governments will abstain from making any financial contribution that is intended to ensure the survival of air carriers.
  (Recommendation 11.5)

- The federal government will amend legislation to make rail track accessible to all qualified passenger carriers who are willing to pay for what they use and will ensure that all such carriers have access to essential rail infrastructure and are treated equally in the movement of their traffic.
  (Recommendation 6.7)
- After a 10-year transition period, all passenger train routes will be unsubsidized and open to any carrier who is "fit, willing and able."
  (Recommendation 12.4)
- Airport and municipal authorities will cooperate to ensure unrestricted access to airports by all ground connectors who pay their share of the costs, and the federal government will similarly grant all ground connectors open access to federally owned airports and rail stations.
  (Recommendation 15.1)
- The federal government will require that all agreements for the sale or lease of federally owned transportation infrastructure include provisions that oblige the operating authority to grant open access to all intermodal connectors on equal terms and conditions.
  (Recommendation 15.2)

Under current international arrangements, if a Canadian air carrier is no longer owned and controlled by Canadians, its designation as a "national airline" and, consequently, its ability to fly international routes, can be challenged. Although restrictions on ownership do not apply to other modes, we propose to limit foreign ownership for the Canadian air carrier industry because of the current international regulatory regime.

Specifically:

- The federal government will retain the existing limits on foreign ownership and control of air carriers.
  (Recommendation 11.1)

- If faced with a potential reduction to only one major Canadian air carrier, the federal government will override limitations on foreign ownership and control for the explicit purpose of, and to the extent required to, ensure competition in the domestic market. (Recommendation 11.6)

## CHANGES FOR PROVIDERS OF INFRASTRUCTURE

**Terminals, links and traffic control services will be priced on a terminal-by-terminal, link-by-link and service-by-service basis.**

**(Recommendation 4.6)**

**Where there is sufficient competition, or where users are in a strong bargaining position with providers of terminals, links or traffic control services — and so long as there are appropriate charges for environmental damage, safety and accidents — competition and market forces will determine prices and investment decisions for passenger transportation infrastructure.**

**(Recommendation 4.7)**

**Where regulations are required, they will be designed to ensure that pricing and investment decisions will be similar to what would otherwise occur through competitive market forces.**

**(Recommendation 4.8)**

### Setting Prices

Travellers will only pay for what they use. Prices will reflect the travellers' or carriers' use of each terminal, link or traffic control service and will be designed to encourage neither over-use nor under-use. Travellers using only some parts of the system will not pay for the parts they do not use and from which they do not benefit. Where such prices will not recover the full cost, they will be adjusted to provide for full cost recovery in such a way as to minimize the loss of efficiency.

Specifically:

- Provincial and territorial governments and road agencies will consider conventional tolling systems when new or expanded limited-access highways are required, with tolls set to cover any costs of the road link in question that exceed those recovered by fuel taxes. (Recommendation 5.6)
- Provincial and territorial governments will institute weight-distance taxes for trucks as part of an overall road-financing program. (Recommendation 5.5)
- Airport operators will obtain their funding from site-specific charges on an airport-by-airport basis, rather than through an allocation from the Air Transportation Tax. Charges to travellers will reflect the commercial potential of the airport, not historical costs. (Recommendations 5.1 and 5.3)
- The operator of the air navigation system will obtain funding for the system by charging aircraft operators directly for their share of air navigation and air traffic control costs through charges that differ by type of flight, class of aircraft and value of benefits received, rather than through an allocation from the Air Transportation Tax. This system will replace the Air Transportation Tax. (Recommendation 5.7)

A decision to move to a link-by-link charge for the existing road system will be based, in part, on technological feasibility, administrative cost and public acceptability. Such a change will likely be gradual or come in stages, except for a limited number of new toll roads.

Specifically:

- Provincial and territorial governments will meet the costs of their highway system, and any agreed upon National Highway System projects within their borders, through fuel taxes and other charges. (Recommendation 6.6)

**Making Investment Decisions**

Investments will be made only in those projects in which benefits to travellers exceed costs, and that yield the highest level of benefits over costs, regardless of mode. In making investment decisions, all costs, including safety, accident and environmental costs, as well as interest on funds invested, will be taken into account. Adequate provision will be made for maintenance. New technologies will be considered along with existing technologies, and full consideration will be given to the potential for intermodal operations to contribute to efficiency and ease of travel.

Specifically:

- For transferring airports to Local Airport Authorities, the federal government's valuation of existing airport capital facilities will reflect the commercial potential of the facilities, not historical costs. (Recommendation 5.3)
- Governments or Local Airport Authorities will make airport investments on an airport-by-airport basis and will only make new airport investments where costs, including a return on investment, can be expected to be repaid through future revenues. (Recommendations 5.1 and 5.3)
- In determining the extent of restoration and upgrading of the national highway network, provincial and territorial governments will be guided by a comparison of benefits and costs on individual projects, rather than by uniform engineering standards. (Recommendation 6.4)

- Governments will invest in high-speed rail infrastructure only if the benefits to the passenger transportation system exceed the costs, and if taxpayers do not have to pay any operating subsidies. (Recommendation 12.6)
- Any railway company will be allowed to abandon any amount of track without a limit (see also Recommendation 6.9). (Recommendation 6.8)
- All responsible agencies, in evaluating safety improvements in different modes, will use comparable values for injury and loss of life. (Recommendation 8.2)

## CHANGES FOR GOVERNMENTS

### The Functions of Government

**Governments will be responsible for establishing policies in relation to the framework, setting and enforcing standards, gathering and reporting information to the public, ensuring a sufficient level of research, maintaining competition and regulating monopolies.**

**(Recommendation 4.9)**

Federal, provincial and territorial transportation departments will move towards being small policy-oriented departments. They will advise governments on policy with respect to government transportation agencies, establish guidelines for project evaluation, notably for the assignment of joint costs to modes and user classes, and will be responsible for taking a cross-modal view of transportation issues. To the extent that environmental and safety policies are tailored to transportation, rather than being of general application, transportation departments will be involved in the development of environmental and safety policies and charges with environmental and health authorities. The departments will shed most or all of their operating responsibilities outside of safety regulation.

Specifically:

- The federal government will transfer all remaining airports to Local Airport Authorities and/or to other types of local operators. (Recommendation 6.1)
- The federal government will convert the air navigation system from a departmental organization to either a Crown corporation or an independent institution. (Recommendation 6.2)
- Each provincial and territorial government will establish a Crown corporation, supplemented by an advisory group, to be responsible for providing roads more efficiently and making pricing and investment decisions more transparent. (Recommendation 6.3)

Government agencies might still be used to provide some carrier services and operate some infrastructure. They would, however, be expected to function without subsidies, and private-sector firms would in general be free to enter the market in competition with such government operators.

In carrying out their policy-making responsibilities, governments will take a long-term view. We expressed concern in our Interim Report, and do again in this report, about a possible loss of important railway corridors as railways streamline their operations and abandon track. Governments will ensure that valuable, irreplaceable corridors are not lost for future transportation use.

Specifically:

- Railway companies will offer abandoned rail rights-of-way, under a formal procedure, to governments and then to other railway companies before such rights-of-way can be converted to other uses. All levels of government will develop policies, based on explicit criteria, for deciding which corridors they wish to retain for future

transportation use and will ensure that land so acquired is maintained intact as a corridor.
(Recommendation 6.9)

The role of government as referee will be expanded, and governments will collect and publish improved data on the passenger transportation system.

Specifically:

- The federal government will review the *Competition Act* and related policy and, if required, will strengthen the powers needed to prevent anti-competitive practices in the intercity bus industry.
(Recommendation 13.2)

- The federal government will extend its regulations governing the anti-competitive practices of computer reservation systems beyond the air mode to take a multimodal approach.
(Recommendation 15.3)

- The federal government will establish the regulations under which any high-speed rail system will operate, including safety and environmental regulations.
(Recommendation 12.8)

- The National Transportation Agency will ensure that abandoned railway corridors are offered to governments or other railway companies at a reasonable price.
(Recommendation 6.9)

- The National Transportation Agency will take more active responsibility for ensuring that transportation services become more accessible to those with disabilities.
(Recommendation 9.4).

- The National Transportation Agency will establish minimum national standards of transportation accessibility for persons with disabilities.
(Recommendation 9.2)

- The National Transportation Agency will mediate disputes regarding the requirement for an attendant to accompany a traveller with a disability.
  (Recommendation 9.7)
- Provincial and territorial governments will implement more-uniform and adequate minimum accessibility standards for inter-city buses for travellers with disabilities, or, if that does not occur, the federal government will rescind its delegated responsibility for nationally applied accessibility standards to ensure more uniformity.
  (Recommendation 9.10)
- Governments will further develop travel and other transportation data for public use, and the federal government will publish an annual report card on the passenger transportation system.
  (Recommendations 16.2, 16.3 and 16.4)

Transferring operating functions from government departments to the private sector or independent agencies will considerably reduce government personnel and financial requirements. We expect that these functions will be carried out with fewer people and at lower cost than is currently the case. Small additional government resources might be required to carry out expanded refereeing functions and to collect improved data on the transportation system. In addition, as the bus industry is brought within the scope of competition review, the federal government may have to increase resources for competition policy. This increase, however, should be more than offset by reductions in the cost of provincial regulatory bureaucracies.

### The Responsibilities of Levels of Government

**Decision making authority of governments will be assigned to the level of government that is both closest to the people and most able to exercise such authority efficiently.**

**(Recommendation 4.10)**

We asked ourselves whether achieving our framework will be possible under the current allocation of responsibilities among levels of government for the different modes.

We recognize that the policies of one level of government regarding a mode for which it is responsible can affect other modes that are the responsibility of another level of government. As long as the affected modes are paying their way, however, this type of interaction is not inherently a problem.

Given current jurisdictional arrangements, good will, cooperation and coordination among levels of government are essential to achieving comparable treatment of different modes. Our framework can be implemented using a cooperative approach, and within existing jurisdictional arrangements.

Specifically:

- A National Highway System will be identified by the Council of Ministers Responsible for Transportation and Highway Safety and will be operated and maintained through cooperative action of provincial and territorial governments and/or their road agencies. (Recommendation 6.5)

Local or regional governments will take policy responsibility for environmental damage when the source and effects are local. Similarly, the federal government will take responsibility when environmental damage from one region affects other regions or countries.

Specifically:

- Local and regional governments will address low-level ozone problems, focussing on ozone non-attainment areas, using special regional regulations such as speed limits, periodic motor-vehicle emissions testing, and emissions surcharges at times of the year when low-level ozone is a problem.
  (Recommendation 7.1)

- The federal government will strive for international agreement on an effective strategy to control global warming, and will seek to harmonize domestic policies and taxes with those of the international community.
  (Recommendation 7.2)

### Treating the Modes Equally

**Governments will tax and regulate all modes equally.**

**(Recommendation 4.11)**

Governments will not treat the modes differently in terms of taxes, charges or regulations. Governments will collect taxes for general revenue purposes from all modes on the same basis, set charges to cover the efficient cost of providing services and facilities and use the revenues for that purpose, and apply charges and regulations equally to all modes to address the costs that transportation activities impose on society.

Specifically:

- All fuel taxes will be used for transportation purposes or as a means of charging for costs, such as environmental damage and health care system costs, caused by transportation.
  (Recommendation 5.4)
- Governments will apply environmental emissions charges equally to all modes and to non-transportation sources, on as close to a per-unit-of-emission basis as practical.
  (Recommendation 7.6)
- Governments will set regulations for the effective control of environmentally damaging emissions that impose similar obligations in terms of cost per unit of abatement on each mode, and that treat

non-transportation sources of pollutants similarly to transportation sources.
(Recommendation 7.3)

- Governments will separate revenues from environmental emission charges from revenues from other passenger transportation charges and use such funds to clean up the environmental damage, compensate those affected, or lower general tax rates. They will not use such funds to expand or maintain the passenger transportation system.
(Recommendation 7.7)

### Improving Accountability and Transparency

**Decision making will be transparent so that Canadians can understand why governments or their agencies make the passenger transportation choices they make, and so that those making decisions can be held accountable.**

**(Recommendation 4.12)**

Those responsible for making and applying the rules and for spending travellers' and taxpayers' money will be more accountable for their actions. Governments will improve accountability by making relevant information available to the public and by making it easy to understand.

Specifically:

- If agencies that are established to manage transportation infrastructure are monopoly suppliers, the level of government responsible will ensure that advisory bodies of travellers and other interested parties are created to counsel management on investment priorities, charging mechanisms and the prices needed to achieve self-sufficiency.
(Recommendation 16.1)

- Governments will clearly report to the public the amount of, and reason for, any continuing subsidies to carriers.
(Recommendations 12.5, 14.4 and 16.4)
- Governments will make public the benefits and costs of any high-speed rail project in which they invest or subsidize and will consult the public on the implication of such investments.
(Recommendation 12.7)
- Government will allocate resources, and provincial and territorial governments will cooperate with the federal government to ensure the further improvement and collection of travel and other transportation data, and the data will be made available to the public.
(Recommendations 16.2 and 16.3)
- The federal government will publish an annual report card on the passenger transportation system that will include information on the use of the system, subsidies, extent of cost recovery, and degree to which objectives are being met, as well as information on the reliability and safety of the passenger transportation system.
(Recommendation 16.4)

## TRANSITION REQUIREMENTS

**In cases where time is required to ease the problems caused by steep price adjustments, or where a carrier, a particular carrier service, a terminal or a link is given another chance to survive within the new framework, financial assistance will be designed to encourage adjustment.**

**(Recommendation 4.13)**

**If a carrier, a particular carrier service, a terminal or a link cannot survive despite a reasonable period of time for adjustment, the terminal or link will be closed or the service discontinued.**

**(Recommendation 4.14)**

Since the passenger transportation system that will result from our framework will differ from the current system, governments will give travellers, carriers and facility providers time to adjust. In this adjustment period, any remaining subsidy from the taxpayers will be:

- provided, where possible, to move people in the most efficient way, regardless of mode;
- provided and managed by the level of government that has responsibility for the mode in question;
- borne by taxpayers in the jurisdiction that makes the decision, not by other transportation users; and
- provided on a declining basis, for a reasonable adjustment period, and then terminated.

Even when they are given financial assistance and a reasonable time to adjust, some carriers or facilities might not be able to achieve commercial viability. In such cases, they will be closed down.

We recognize four cases in which governments may have to provide transitional subsidies.

Specifically, they are:

- *Airports:* Whenever applying our principles to airports, including all Transport Canada airports, will result in steep increases in average charges to travellers, governments will provide transitional subsidies to be phased out over 10 years. The initial level of subsidy will be based on the current operating subsidy and will be used for capital as well as operating expenditures or, if the airport is closed, for other local transportation purposes.
  (Recommendation 5.2)
- *Passenger rail:* The federal government will enact legislation to give VIA Rail a mandate to operate on a commercial basis, with the general subsidy having a sunset provision of 10 years. During this

period, VIA Rail will have greater freedom to manage, including investment decisions, route selection, service levels and pricing; will be allowed to compete for other services such as commuter services and transporting mail; and will be required to file and publish detailed annual operating plans and financial reports, including the costs and revenues related to individual routes. At the end of 10 years, all routes will be unsubsidized (see also discussion of remote services later in this section).
(Recommendations 12.1, 12.2, 12.3 and 12.4)

- *Intercity bus:* If necessary to avoid steep increases in bus fares on particular routes following the relaxation of economic regulation of the intercity bus industry, governments will provide transitional subsidies on a declining basis not to exceed 10 years.
(Recommendation 13.3)
- *Ferries:* If necessary to avoid steep increases in fares, governments will provide transitional subsidies not to exceed 10 years on individual ferry routes (see also discussion of constitutionally provided ferry services later in this section).
(Recommendation 14.1)

In some cases, governments might choose to continue subsidies to passenger transportation services that are not commercially viable. Such subsidies are not consistent with our framework and, in general, should not be maintained. If, however, governments continue to provide subsidies despite our recommendations, they will do so in such a way as to ensure that services are as efficient as possible. In addition, such subsidies will be provided from general tax revenues and not from charges to travellers.

Specifically with respect to:

- *Remote train service:* Governments may decide to continue providing passenger transportation service to some communities that currently have remote train service. In this case, governments will use the most efficient mode and carrier, and, if feasible, use competitive bidding to choose the mode and carrier. In addition,

governments will provide the subsidy in such a way that the subsidized carrier will bring passengers to transfer at the closest convenient point to a commercial, unsubsidized carrier.
(Recommendation 12.5)

- *Constitutionally provided ferry services:* The federal government may use subsidies, if required, to maintain constitutionally guaranteed ferry services. Except for the ferry service between North Sydney, Nova Scotia, and Port aux Basques, Newfoundland, for which there is a constitutional limit on rates, continuing taxpayer subsidies to other ferry services will be no higher than required to maintain the service. In the case of the Nova Scotia to Newfoundland service, and any other constitutionally guaranteed services that require taxpayer subsidies to continue, the federal government will strive for the highest degree of cost recovery consistent with the constitutional obligations, and may offer the affected province a federal grant instead of the subsidy.
(Recommendation 14.2)

## MEETING OUR OBJECTIVES

In Chapter 4, we stated that the goal of the passenger transportation system should be to move people to where they want to go, and we proposed:

**Four guiding objectives:**

- **safety;**
- **protection of the environment;**
- **fairness to taxpayers, travellers and carriers; and**
- **efficiency, so that services are provided only where benefits to the individual traveller equal or exceed the cost, and given levels of service are provided at the lowest possible cost.**

**(Recommendation 4.1)**

We also concluded that:

**Governments pursue nation-building and regional development objectives through other programs rather than using the passenger transportation system.**

**(Recommendation 4.2)**

Our recommendations will create a passenger transportation system that is safe, that is more protective of the environment, that ensures fairness to taxpayers, travellers and carriers, and that operates more efficiently.

## IMPROVING SAFETY

We are encouraged by long-term trends in transportation safety, which show impressive improvements in all modes. We also recognize that safety improvements demand innovation — new technologies and new attitudes and behaviour by carriers and travellers. Our framework encourages such innovation.

### Government Regulations

Governments have been responsible for many safety improvements: in vehicles, by regulating vehicle performance; and in infrastructure, by adopting design standards. We recognize that such actions have generally been effective, and our framework reaffirms the role of government in maintaining the safety of the system through regulations. Our recommendations will strengthen the role of governments in providing objective analysis of accident trends and potential safety measures. Further, we have recommended that governments use comparable values for injury or loss of life for all modes when they establish regulations or invest directly in transportation infrastructure. This will help achieve a coordinated approach to safety among branches and levels of government.

### Using Charges to Change Behaviour

The payments that carriers and travellers already make toward accident costs, either directly or through insurance systems, have provided strong incentives for personal and corporate improvements in safety and have contributed to overall long-term improvements. Currently, however, carriers and travellers do not pay all the costs associated with accidents and safety prevention programs. Under our framework, governments will encourage greater safety by:

- making the safety costs of transportation as transparent as possible;
- ensuring that travellers and carriers pay all the costs of accidents by having provincial and territorial health-insurance systems reclaim all costs of treating accident victims from companies insuring vehicles and carriers; and
- ensuring that travellers and carriers pay all prevention costs by charging travellers and carriers directly for the costs of government transportation safety programs, such as emergency rescue services, police traffic enforcement and the administrative costs of regulating safety. In addition, users will pay for the safety components built into infrastructure by means of appropriate pricing for such infrastructure.

### Conclusions on Safety

We are convinced that when travellers and carriers face the full costs of accidents and safety programs, they will change their behaviour to reduce accidents. We also expect that the discipline involved in objectively assessing risks, evaluating safety measures, and providing accountability and transparency in setting charges will encourage governments to treat the modes with greater consistency, thereby getting the most safety improvement per dollar spent.

## GREATER PROTECTION OF THE ENVIRONMENT

Efforts to protect and improve Canada's environment have moved forward on many fronts in recent years. Public support for environmental programs has grown, encouraging increases in government spending and the regulation of individual and corporate activities. In addition, governments have attempted to coordinate their activities through the Canadian Conference of Ministers of the Environment, and the federal government has cooperated with other countries in environmental protection.

### Government Regulations

Under our framework, current regulatory controls will continue where they are cost-effective and will apply to all modes equally. Coordination among governments will be further improved by using common standards for environmental costs when evaluating regulations and investments in transportation infrastructure.

### Using Charges to Change Behaviour

In a more radical addition to the current approach, our principles call for travellers, carriers and providers of infrastructure to pay the environmental costs of travel and transportation investments. Making the environmental consequences of transportation obvious through transparent charges will considerably improve the strength and consistency of efforts to protect the environment. Carriers and travellers will take environmental damage into account in a consistent way when making transportation decisions.

Carriers and travellers will make such decisions by applying the same benefit-cost test that governments will apply in their decisions on regulations and public investments — that is, they will ask "Is the benefit worth the cost?" Since carriers and travellers will be using a common set of valuations of environmental damages — the same set as used by governments in their environmental decisions — consistency and efficiency in achieving environmental goals will be promoted. Governments will not need to predict where and how carriers and travellers should achieve reductions. The decisions can be left to users.

We are aware that the ability to measure environmental damage and assess its costs is limited and that (as in the case of other ill-defined risks) misperceptions of possible effects of preventive actions lead to a great range of public opinions — from indifference to strident demands for the strongest measures. We also recognize that political agreements on national goals might themselves be based on misperceptions. We argue strongly that governments ensure that the scientific evidence for environmental problems and solutions, and the most objective assessment of such evidence, be disseminated to the public as widely as possible.

Under our framework, governments will use revenues from environmental charges to clean up damage and to compensate those affected by such damage. Substantial surpluses, however, will remain. For example, governments will gain revenues from carbon dioxide ($CO_2$) emission charges, but it is unlikely that people at risk from global warming will be identified or compensated individually. Governments will use surplus environmental revenues to benefit all Canadians by reducing general taxes.

### Conclusions on Protecting the Environment

We recommend that travellers and carriers pay the costs of the damage they impose on the environment. We base this recommendation in part on the belief that users are generally able to affect the amount of damage they cause by their choice of vehicle or amount and type of travel.

We also believe that environmental charges will make the passenger transportation system more fair by guaranteeing that users provide compensation to taxpayers for the environmental costs that their use of the passenger transportation system imposes. Those who travel less will not pay the environmental costs imposed by those who travel more. Carriers and others who save money by using more-polluting vehicles will not gain an automatic competitive advantage over those who invest in pollution reduction. Travellers and carriers in the various modes will not be subject to different regulatory standards.

While our recommendations call for radical change, we believe they are rational, fair and will achieve national environmental goals efficiently and at a lower overall cost.

## GREATER FAIRNESS TO TAXPAYERS, TRAVELLERS AND CARRIERS

Our recommendations are guided by the objective of fair treatment for all Canadians. In general, under our framework, transportation policy will be neutral in its treatment of individuals and identifiable groups of individuals, favouring none above others, and favouring no group identified by region or by shared activities. All Canadians will have access to the transportation system on the same terms.

Specifically:

- governments will remove any barriers that prevent "fit, willing and able" carriers from entering transportation markets and getting access to essential facilities;
- governments will not favour travellers over non-travellers by providing large subsidies to some travellers; and
- governments will treat carriers and travellers in different modes equally.

### Special Circumstances

We recognize three special circumstances in applying these general rules of fairness:

- *People with disabilities:* Under our framework, travellers with physical or mental disabilities will have opportunities to use public passenger transportation that are similar to those enjoyed by all

Canadians. Carriers will make a sufficient proportion of their new intercity transportation vehicles accessible to people with disabilities, and will ensure that travellers with disabilities are treated with sensitivity and understanding.

- *Constitutionally provided ferry services:* The federal government is obliged under the Constitution to assume responsibility for certain ferry services and, in one case, to maintain a limit on rates. Governments will apply our recommendations on the management of infrastructure, and may institute competitive tendering to carriers for these ferry services. The result will be services provided in as cost-effective a manner as possible, thus reducing the amount of taxpayer support required.
- *Certain non-viable facilities and services:* There may be circumstances in which governments decide that a commercially non-viable transportation facility or service should be provided or guaranteed. Again, governments will apply our recommendations on the management of facilities, and may institute public competitive tendering to carriers for these facilities and services. This will reduce subsidies.

### Eliminating Subsidies

In general, subsidies from taxpayers and transportation users to certain groups of travellers are unfair — for example, air travellers being supported by non-travellers for the costs of air navigation systems and airport expenses or train travellers being supported by direct subsidies from taxpayers for their ticket. This unfairness is compounded by its effect on travel behaviour. Subsidies from taxpayers make some transportation services cheaper, encouraging travellers to use them more and — to the extent that the subsidy is above the average for transportation — causing travellers to switch from other modes. Such subsidies to one mode are unfair to other modes that could offer competing services.

The remedy is straightforward. Under our framework, carriers, and ultimately travellers, will pay all of the costs of infrastructure and services. This remedy will also apply to those modes that receive large subsidies — passenger train services and those ferry services for which there are no constitutional obligations. For example, our estimates show that passenger train services receive payments from taxpayers far in excess of fares received from travellers, while the public gains little if anything in terms of environmental improvement from these large expenditures. Such subsidized train services also compete unfairly with services provided by other modes, particularly intercity bus carriers.

Appropriate charges for environmental damage will also make the transportation system more fair than it is at present, even where there are no simple administrative systems for identifying those who bear the damage and for providing them with compensation. Where the evidence shows that the environmental damage differs substantially by region, as is the case with low-level ozone, and if feasible administratively, it would be fairer to differentiate the charges by region.

### Conclusions on Fairness

Under our framework, the goal of the passenger transportation system is to move people to where they want to go. Taxpayers should not be required to support one mode when a cheaper mode is available. Such support is unfair to taxpayers and to the operators and users of the other modes.

## A MORE EFFICIENT TRANSPORTATION SYSTEM

### Competition and Innovation

The passenger transportation system will be made more efficient, delivering better service at lower costs, through reforms in management, pricing policies and investment decision making.

We are convinced that competition will spur innovation. Our recommendations, therefore, introduce competition wherever possible: competition among modes, among carriers within modes and, where relevant, among providers of facilities. For example, improving ease of entry by bus carriers will reduce costs and fares, improve services on trunk routes and allow lower-cost operations to offer new services to smaller communities. Ensuring that competing carriers get access to air and bus terminals, train stations and computer reservation systems will encourage innovation and cost-cutting, to the benefit of all travellers.

In addition, our recommendations on the transparency of the budgeting processes of agencies, and on advisory roles for users of infrastructure provided by agencies, will encourage providers of infrastructure that are not subject to much direct competition to continually seek innovations that improve service and lower costs.

### Commercialization of Services

Putting transportation infrastructure and carriers on a more commercial basis will lower costs and improve services to carriers. For example, commercialization of air navigation services will free management to pursue innovation and improved efficiency.

For constitutionally guaranteed ferry services and for any remote train services that governments judge to require continuing taxpayer support, tendering by open contracts will allow competing operations to demonstrate their efficiency. It will also provide travellers and taxpayers with the best service at the least cost.

### Pricing and Investment

Requiring travellers to pay the full costs of their travel and removing taxpayer subsidies are important components of our proposals for efficiency. Equal treatment of modes and carriers means that users pay prices that represent the true costs of services, with no hidden contribution from others such as taxpayers and victims of environmental damage.

Our recommendations for pricing and investment are intended to achieve efficiency in the transportation system. Carriers and infrastructure providers will design efficient pricing systems, subject to the requirement that they recover all costs. With appropriate pricing in place, travellers and carriers will make decisions that maximize the benefits from travelling. Similarly, consideration of social costs and benefits, without regard to mode and jurisdictional limits, will guide agencies in setting priorities for investments in public transportation infrastructure.

### Conclusions on Efficiency

As we have emphasized throughout this report, efficiency is achieved whenever Canadians make the most of the resources that are devoted to transportation, and devote the amount of resources to transportation that wastes neither opportunities nor money. An efficient transportation system is one that contributes the most to Canadians' standard of living.

## REACHING OUR DESTINATION

No one can predict the future with any accuracy. In looking ahead, we see many changes that could affect intercity passenger transportation. For example, the environmental costs of transportation-related pollutants may prove substantially higher or lower than currently estimated, public demand may shift toward the train or the bus, and new technology may expand road capacity, reduce the environmental costs of car use, and make air travel cheaper. The possibilities for change are infinite.

What we set out to do was to develop principles under which travellers, carriers and governments will achieve what we believe are widely held objectives in a broad range of circumstances. Our principles will ensure a framework in which costs are reflected in prices paid by travellers, and institutions are flexible and responsive. This framework will constrain transportation activities that become too costly relative to benefits provided, and will encourage the transportation industry to take advantage of new opportunities resulting from improved technology and other favourable developments.

# APPENDIX A

## ORDER IN COUNCIL

P.C. 1989-2096

Certified to be a true copy of a Minute of a Meeting of the Committee of the Privy Council, approved by Her Excellency the Governor General on the 19th day of October, 1989.

The Committee of the Privy Council, on the recommendation of the Prime Minister, advise that a Commission do issue under Part I of the Inquiries Act and under the Great Seal of Canada appointing:

Louis Davies Hyndman of Edmonton, Alberta
Marie-Josée Drouin of Montreal, Quebec
Susan A. Fish of Toronto, Ontario
Marc Gaudry of Montreal, Quebec
William P. Kelly, C.M., of Ottawa, Ontario
John B. Hamilton, Q.C. of Toronto, Ontario
John Forbes Helliwell of Vancouver, British Columbia
James D. McNiven of Halifax, Nova Scotia
Dr. Maurice LeClair, O.C., M.D., of Westmount, Quebec

together with such other persons as may be named from time to time, to inquire into and report upon a national integrated inter-city passenger transportation system to meet the needs of Canada and Canadians in the 21st century and to ensure that transportation links among Canada's regions and communities are maintained and improved; and

The Committee also advise that the study include an examination of

(a) the role of a national integrated inter-city passenger transportation system, in the context of

- the relationship of the inter-city passenger system with the whole transportation system;
- the current extent and state of Canada's inter-city passenger transportation system;
- demographic and population trends;
- social trends and user preferences;
- technological developments in the transportation industry;
- international transportation developments and how they could impact on Canada's competitiveness;
- the economic prospects for the Canadian economy and their likely impact on inter-city passenger transportation requirements;
- the mobility needs of Canadians;

...2

(b) the structure of a national integrated inter-city passenger transportation system for transportation by air, marine, highway and rail and the relations among the modes, taking into account

- the means to encourage Canadians to travel within Canada;
- the appropriate mix among the various modes so as to maximize the effectiveness, efficiency and competitiveness of the system;
- the financial implications of such a system, including initial capital requirements as well as the cost of maintaining and operating the system;
- the promotion of energy efficient means of transportation;
- the environmental impact of various options in order to achieve a balance between the environmental impact and the transportation needs of Canadians;

(c) the potential for and the constraints on achieving a national integrated inter-city passenger transportation system by

- advising on the institutional arrangements required, including any arrangements needed to rationalize and coordinate the respective roles of the three levels of government in Canada in the provision of inter-city passenger transportation services;
- examining the relevant labour relations environment;
- assessing the transportation industry-government interface;

.../3

(d) the appropriate financial arrangements to achieve a national integrated inter-city passenger transportation system by

- taking into account the jurisdictions of the different levels of government and the role of the private sector;
- taking into account the overall cost to Canadians;
- considering the concept of appropriate user shares;
- examining means of attracting private financing to major transportation projects; and

The Committee also advise that the Commissioners

(1) be authorized to adopt such procedures and methods as they may from time to time deem expedient for the proper conduct of the inquiry and to sit at such times and in such places as may be required;

(2) be authorized to rent such space and facilities as may be required for the purposes of the inquiry, in accordance with Treasury Board policies;

(3) be authorized to engage the services of such experts and other persons as are referred to in section 11 of the Inquiries Act, at such rates of remuneration and reimbursement as may be approved by the Treasury Board;

(4) be directed, within the ambit of their work, to seek the views of all provincial and territorial governments as well as interested Canadians from all walks of life and all regions of the country;

(5) be directed to submit an interim report to the Governor in Council in both official languages not later than eighteen months from now;

(6) be directed to submit a final report to the Governor in Council in both official languages with all reasonable dispatch but no more than three years from now;

.../4

(7) be directed to file the records and papers of the inquiry as soon as reasonably may be after the conclusion of the inquiry with the Clerk of the Privy Council; and

The Committee also advise that Louis Davies Hyndman of Edmonton, Alberta, and Marie-Josée Drouin of Montreal, Quebec, be the Chairman and Vice-Chairman respectively of the Commission; and

The Committee further advise that Janet Smith of Ottawa, Ontario, be appointed Executive Director of the Commission.

2. Changes Expected from 2000 S-Q to 2000 D 325
Endnotes 334

# INTRODUCTION TO VOLUME 2, AND RELATION OF VOLUME 2 TO THE ROYAL COMMISSION'S RESEARCH PROGRAM

Volume 2 is organized as a set of Notes to Chapters 1, 2, 3, 6, 7, 8, 9 and 18 of Volume 1. The primary purpose of these notes is to explain more fully, and to document, the estimates of the amounts and costs of intercity passenger travel that were developed for this report and are used in Volume 1. Such estimates figure prominently in the analysis of current and potential future passenger transportation costs in Chapters 3 and 18 of Volume 1, in the discussion of environmental impacts of transportation in Chapter 7, and in the discussion of the accident records of the different modes of transportation and of accident costs in Chapter 8. Estimates developed by Royal Commission staff are also used in the reference to total resources devoted to transportation in Chapter 1, and, in Chapter 2, to the amounts of intercity travel by various modes, currently and historically in Canada and in other countries.

In addition, Volume 2 provides supporting material for the section on rail infrastructure in Volume 1, Chapter 6, and for the discussion of legislation, regulations and other developments relevant to the provision of transportation for people with disabilities in Volume 1, Chapter 9.

Many of the estimates developed for this report and used in Volume 1 are inevitably quite rough, and in some cases are based on particular assumptions where alternative assumptions would also have been defensible. The relevant sections of Volume 2 do not quantify the margins of uncertainty to which the various estimates are subject. It is hoped, however, that the presentation and discussion of the approaches used in developing the estimates will allow the reader to form a general impression of the margin of uncertainty, and of the sensitivity of the estimates to key assumptions.

In some cases the notes to a chapter are presented as an integrated discussion of the development of the quantitative estimates in that chapter. In other cases, the notes deal with a series of relatively independent points in the chapter. A detailed table of contents precedes each of the sets of chapter notes.

A substantial part of the contracted research, and of the staff research work, carried out for the Royal Commission contributed to the development of the estimates, particularly the comprehensive cost estimates for the different modes of intercity transportation. Volumes 3 and 4 contain 22 of the research papers prepared for the Royal Commission that were judged to be particularly relevant to the issues discussed in Volume 1 and/or to be of interest to a significant number of readers in the transportation field. In some cases, sections of Volume 2 build on material from papers in Volumes 3 and 4. Some research papers in Volumes 3 and 4 provide a self-contained development of certain estimates and analyses referred to in Volume 1, particularly in Chapters 11, 12 and 13. No further supporting material is provided for these chapters in Volume 2. Several of the papers in Volumes 3 and 4 are summaries of historical, analytical or empirical work that provide a general discussion of issues of interest to the Royal Commission, and are relevant to one or more chapters in Volume 1.

These papers are listed below in the order in which they appear in Volumes 3 and 4.

| RR-10 | Richard J. Schultz | Airline Subsidies: Three Case Studies |
| RR-11 | M. Brenckmann | Technological Innovation in Transportation R&D Funding Policy and Approach |
| RR-12 | ADI Limited | Analysis of National Highway System Proposals |
| RR-13 | Ron Hirshhorn | The Ownership and Organization of Transportation Infrastructure — Roads and Airports |
| RR-14 | Robert Leore | Intercity Passenger Transportation Data Compendium |

A number of additional reports were prepared by contractors and Research Division staff. These are included in the Royal Commission material transferred to the National Archives. Several of these papers were prepared relatively early in the Royal Commission's work program and were used as inputs in subsequent work.

# NOTES TO CHAPTER 1:
# RESOURCES DEVOTED TO TRANSPORTATION

INTRODUCTION 2

1. THE ESTIMATES 3

2. COMPARISON WITH RESOURCES DEVOTED TO HEALTH CARE 17

3. VALUE ADDED BY TRANSPORTATION CARRIERS 17

4. ESTIMATE OF RESOURCES DEVOTED TO INTERCITY PASSENGER TRANSPORTATION 19

# INTRODUCTION

Chapter 1 of Volume 1 states that in 1989 Canadians devoted resources equal to about 16% of the gross domestic product (GDP) to transportation, of which about 5% to 7% of GDP — depending on how broadly intercity travel is defined — was for intercity travel. These Notes to Chapter 1 introduce the concept of resources devoted to transportation, and sketch the way in which the estimates were derived.

The concept — total resources devoted to the transportation function or activity — is a very broad, and somewhat unconventional, measure of the size of transportation in the economy. It is used by the United States Department of Transportation (*National Transportation Statistics,* 1990, figure 1, p. 4) and the Eno Foundation (*Transportation in America,* 8th edition, May 1990, pp. 5-6) in discussions of transportation in the United States economy. A very similar concept was recently used in an article by Pierre Zalatan and Jean-Pierre Roy of Transport Canada ("The Importance of Transportation in the Canadian Economy," *Evolution in Transportation; Proceedings of the 26th Annual Meeting of the Canadian Transportation Research Forum,* Quebec City, May 1991, pp. 422-435).

The concept is somewhat unconventional because it includes resources devoted to production both of transportation services that are components of final demand, and transportation services (especially freight) that are intermediate inputs used in the production of other goods and services. Although the concept of total resources devoted to the function of transportation is of interest in arraying information on transportation resource use, it is important to recognize the consequences of including both final and intermediate activity.

If parallel estimates were made of the total resources devoted to a range of other major functions or activities in the economy — for example, to manufacturing, distribution, health care, education, public administration and so on — as well as to transportation, the total resources devoted to all these functions could well exceed the conventional measure of the total use of resources in the economy —

the GDP. This is because transportation, as well as being a final product, is an input in most of the other functions including manufacturing, education and health care. Similarly, goods or services produced by several of the other functions are used in carrying out the transportation function. The notion of total resources devoted to an economic function or activity departs from standard national income and expenditure accounts concepts, which generally focus either on final uses (rather than final plus intermediate uses) of goods and services, or on value added by (rather than total resources devoted to) economic activities or "industries." The National Accounts thus avoid counting use of resources more than once when displaying data on the full range of economic activities.

## 1. THE ESTIMATES

The special nature of the estimates of total resources devoted to transportation having been acknowledged, their derivation will be sketched. The objective is to obtain rough estimates of resources devoted to transportation; thus approximate procedures are used at a number of stages. In addition, to the extent possible, the estimates in this section use published data directly. In this they differ from some of the cost estimates in Chapter 3 of Volume 1 where attempts are made to quantify concepts that are judged to be important when comparing comprehensive costs of the different modes of transportation, but for which standard published data are not currently available.

Because individuals, businesses and governments are all involved both in purchasing transportation services and in directly using resources for transportation purposes, it is necessary to assemble data and estimates from a variety of sources to obtain an estimate of total resources devoted to transportation. Table 1(2)-1 shows four broad components of use of resources for transportation purposes:

I. Transportation services produced by business for sale (carrier revenues);

II. Transportation services produced by businesses for their own account — excluding business use of cars;

III. Own account car expenditures; and

IV. Government capital and operating expenditures to support transportation.

*Table 1(2)-1*

6. *Taxicabs: 1980–1987:* Statistics Canada, *The Input-Output Structure of the Canadian Economy 1987,* Catalogue No. 15-201, February 1991, Table A; *1988:* Statistics Canada, *The Input-Output Structure of the Canadian Economy 1988,* Catalogue No. 15-201, January 1992, Table A.
Note: The figure shown is for GDP in current dollars at factor cost rather than total revenues. However, most purchased inputs for the taxi industry are in principle included in component III.

7. *Pipelines: 1980–1987:* Statistics Canada, *Corporation Financial Statistics,* Catalogue No. 61-207, Table 2B; 1988–1989: Estimates based on unpublished material from Statistics Canada.

*II. Transportation services produced on an own account basis — excluding car*

9. *Private trucking* — based on published data: *1982–1983:* Unpublished data from Statistics Canada; *1984–1988:* Statistics Canada, *Trucking in Canada,* Catalogue No. 53-222.
Data extrapolated to 1989 (given reduced coverage of 1989 published data) and to 1980 and 1981.

11. *Private marine: 1980–1989:* Statistics Canada, *Shipping in Canada,* Catalogue No. 54-205, Table 2, line 14 (1980–1984), Figure 8.5 (1985), and Figure 8.3 (1986–1989).

12. *Pipelines — own account: 1980–1987:* Statistics Canada, *Corporation Financial Statistics,* Catalogue No. 61-207, Table 2B; *1988–1989:* Estimates based on unpublished material from Statistics Canada.
Estimate is based on difference between value of sales of products and value of raw materials purchases.

13. *Allowance for private air:* See text — estimate for United States private air is from F. Smith, *Transportation in America* (Eno Foundation, Westport, Conn., May 1990), p. 6.

*III. Car — own account*

*A. Expenditures on new and used (net) motor vehicles*

15. *Personal: 1980–1989:* Statistics Canada, *National Income and Expenditure Accounts, Annual Estimates, 1980–1991,* Catalogue No. 13-201, August 1992, Table 52, pp. 66–67.

16. *Residual:* The difference between 17 and 15.

**17.** ***Subtotal: 1980–1989:*** **Statistics Canada, *New Motor Vehicle Sales,* Catalogue No. 63-007, Vol. 63, No. 10, August 1992, Table 9.**
**Adjusted to include an allowance for dealer margins on used cars which would be included in 15 — assumed to be 10% of line 15.**

***B. Expenditures on gasoline***

**18.** ***Personal:*** **See item 15.**

**19.** ***Residual:*** **The difference between 20 and 18.**

**20.** ***Subtotal:*** **Quantities of gasoline sold — 1980–1989: Statistics Canada, *Road Motor Vehicles, Fuel Sales,* Catalogue No. 53-218, Table 1.**
**Average fuel prices — *1980–1989:* Unpublished data from Energy, Mines and Resources. The price of regular unleaded gasoline was used to estimate the total value of gasoline sold.**
**Gasoline for car use is assumed to be 95% of total road gasoline sales less an allowance for share of light truck use not related to passenger transportation (20% of estimated light truck use).**

***C. Other expenditures on car operation***

**21.** ***Personal:*** **See item 15.**

**22.** ***Residual:*** **The ratio of residual to personal spending for vehicles and fuel combined multiplied by line 21.**

***IV. Government capital and operating expenditures to support transportation***

**25.** ***Federal government expenditures: 1980–1986:*** **Statistics Canada, *Federal Government Finance, Revenue and Expenditure, Assets and Liabilities,* Catalogue No. 68-211, Table 2; *1987–1989:* Unpublished data from Public Institutions Division, Statistics Canada.**

**26.** ***Provincial/local expenditures:***
**Residual derived from total consolidated government expenditures on transportation less federal government expenditures. (Thus, the provincial/local expenditures figure is a consolidation of provincial/local expenditures less transfers from federal government tied to transportation programs.)**
**Total Consolidated Government Expenditures — *1980–1982:* Statistics Canada, *Consolidated Government Finance,* Catalogue No. 68-202, Table 2; *1983–1989:* Unpublished data from Public Institutions Division, Statistics Canada.**

**27.** ***Road policing and safety:***
**Royal Commission staff estimates — road policing estimate (see section 5.1.4 of Notes to Chapter 3 in this Volume) approximately doubled to allow for other related spending by non-transport departments on motor vehicle registrations, control and safety.**

***V. Deductions to eliminate double counting***

***A. Consolidated government transportation revenues***

*31.* ***Motive fuel taxes: 1980–1989:*** **Statistics Canada, P*ublic Finance Historical Data, 1965/66–1991/92,* Catalogue No. 68-512, March 1992, Table H1 (Federal) and H3 (Provincial).**

**With provincial revenues adjusted approximately to remove revenues that would have been generated if standard provincial sales tax rates were applied to motive fuels (since such fuels are generally exempt from provincial retail sales tax).**

*32.* ***Air transportation tax: 1980–1983:*** **Statistics Canada, *Consolidated Government Finance,* Catalogue No. 68-202, Table 1 and unpublished material from Public Institutions Division, Statistics Canada; *1984–1989:* Supply and Services Canada, *Public Accounts,* Volume 2, Transport Canada section.**

*33.* ***Motor vehicle permits: 1980–1985:*** **Statistics Canada, *Consolidated Government Finance,* Catalogue No. 68-202, Table 1 and unpublished material from Statistics Canada; *1986–1990:* Statistics Canada, *National Income and Expenditure Accounts, Annual Estimates, 1980–1991,* Catalogue No. 13-201, August 1992, Table 44, line 15, and Table 45, line 2.**

## I. Transportation services produced by business for sale (carrier revenues including direct government subsidies)

The table shows revenues for the major categories of carriers. Sales revenues are used as a measure of total resources devoted to producing these transportation services.

Revenues of travel and ticket agents, and of car and truck rental operations, might also be considered for inclusion in a broad measure of transportation. The data on carrier revenues, however, are generally reported before deducting commission charges of agents; thus a considerable portion of agent commissions is already included in carrier revenues. Much of the revenues of car and truck rental operations, which totalled about $3 billion in 1989, will in principle be captured in the estimate of resources devoted to private trucking and car use in components II and III.

### II. Transportation services produced by businesses for their own account — excluding business use of cars

Businesses and governments devote substantial "in-house" resources to transportation in addition to being major customers for the services of transportation carriers (the latter purchases are included in component I).

These in-house transportation activities are divided into:

- private trucking;
    - based on published data; and
    - adjustment for incomplete coverage
- own account marine transport;
- own account pipeline use; and
- allowance for business aircraft.

As set out in the note on sources to Table 1(2)-1, some data are available for Canada on the first three categories of own account transportation activity. The reported data seem very likely, however, to underestimate substantially the total resources devoted to private trucking. An allowance for incomplete coverage of private trucking is thus added, which is equal to 1% of GDP for all years. This adds an amount somewhat higher than the published data for expenditures on private trucking in the later years covered by the table; it is believed to be a conservative allowance. Road diesel sales not accounted for in the published statistics on diesel fuel use by for-hire truck, private truck, and bus are roughly equal to the amount that is accounted for by such sales, and are more than twice the level of reported sales to private trucking alone. This suggests that private trucking activity not covered in the official statistics is likely to be larger than private trucking activity which is covered.

There are no comprehensive data on business use of company-owned aircraft. Aviation gasoline sales data coupled with data on fuel consumption by carriers, suggest a substantial level of aviation activity by other than carriers. The allowance made is .1% of GDP, a level somewhat lower than estimates for the United States.

Data on business and government use of cars are not readily available. This category has been dealt with on the basis of overall data on cars, and is included as part of component III.

### III. Own account car expenditures

Travel by car is the predominant means of urban and intercity travel in Canada. (As is the practice throughout this report, car refers to both passenger automobiles and light trucks used for passenger transportation purposes.) Data are available for total consumer expenditure on car purchase and operation including maintenance and repairs, fuel, insurance and licence fees. Data are also available which permit estimates of the total value of new car sales, and of gasoline sales.

The residuals, when one deducts the value of car sales (including net sales of used cars) to consumers from the total value of car sales and deducts gasoline sales for car use to consumers from total gasoline sales for car use, provide estimates of business (including car rental operations) and government expenditures on car purchase and fuel. The "residual" for other car operating expenditures is calculated by applying the average ratio of the residual to consumer expenditure for car purchases and fuel purchases, to consumer expenditures for other car operating costs.

The estimates in the table count investment in new cars in the year of purchase, rather than amortizing the price of the car over its life and include an allowance for cost of capital. The latter approach is followed in deriving the cost estimates of car use in Chapter 3 of Volume 1. The two approaches, however, can be expected to produce quite similar results on average although they could diverge substantially in years of cyclically high or low car sales.

No allowance is made in these estimates (or in the cost analysis in Chapter 3 of Volume 1) for any cost of the driver's time.

### IV. Government capital and operating expenditures to support transportation

Governments use resources to build and maintain transportation infrastructure including roads and airports, to provide air and marine navigation and traffic control services, and to control and police road traffic.

For purposes of the table, an estimate of total government investment and operating expenditures related to the provision of transportation is required. This estimate is derived using data on total recorded government spending on transportation, plus an estimate of spending on road policing and related government enforcement and safety activities occurring outside of transport departments. Direct government subsidies to transportation carriers are then subtracted from total government expenditure on transportation. (The subsidies have been included in the value of sales of carrier services in component I.) Component IV does not include expenditures by government to purchase or provide transportation for use by government; such expenditures should be covered in components I and III.

Intergovernmental transfers relating to transportation programs are excluded to avoid double counting. The treatment of government transportation investment follows the practice of public accounts, that is, investment is recorded in the year the expenditure is made rather than amortized over the life of the asset as in the cost estimates of Chapter 3 of Volume 1.

The estimates of expenditures in components I to IV involve some double counting that should be eliminated in order to calculate total resources devoted to transportation.

### V. Adjustments to eliminate double counting

The charges, fees and special taxes that governments levy on users of some government-provided transportation facilities, and that cover some of the costs of government transportation services (IV), are included in the prices paid for transportation in components I, II and III. Thus, to add total expenditures on transportation in components I, II and III to government transportation expenditures in component IV, would result in double counting. The table subtracts charges, fees and special taxes that governments levy for use of transportation facilities. These are the infrastructure charges and the special transportation taxes and fees discussed in Chapter 3 of Volume 1, and in Notes to Chapter 3 in this Volume. As in Chapter 3, the amounts of provincial gasoline and other motive fuel taxes in excess of standard rates of general provincial sales taxes are considered to be equivalent to user charges for government-provided transportation facilities for purposes of this table.

A second source of double counting arises because the expenditures in components I to IV include, directly and indirectly, some inputs that are already counted in the sales revenues of common carriers (I). For example, the cost of common carrier services (I) and of own account (II and III) activity includes the cost of gasoline and other fuels, some part of which is the cost of transporting the fuel to where it is sold. Such transportation costs for fuel will already be reflected in (freight) carrier sales revenues. The table thus includes an approximate adjustment, based on Statistics Canada Input-Output Accounts data, to eliminate inter-transportation-industry transportation requirements and transportation margins.

Estimated total resources devoted to transportation (VI) are then calculated as the sum of components I through IV, less adjustments to eliminate double counting (V).

Table 1(2)-2 expresses the dollar estimates from Table 1(2)-1 as percentages of GDP. The 15.9% shown for 1989 in the final line of the table is the basis for the statement in Chapter 1 of Volume 1 that resources equal to about 16% of GDP were devoted to all forms of transportation in that year.

The estimation procedures are viewed as adequate to support the conclusion that a substantial portion of the economy's resources is devoted to providing transportation. For several types of carrier, however, the data used in Table 1(2)-1 and Table 1(2)-2 do not cover small operators and thus tend to under-estimate total transportation provided in the sector. The allowances for lack of coverage of much of private trucking, and of own account aircraft operation, are probably on the low side. The approach would need to be refined before the estimates could be used to draw strong conclusions as to changes in the share of resources devoted to transportation over time, or be used to make precise international comparisons.

## 2. COMPARISON WITH RESOURCES DEVOTED TO HEALTH CARE

The discussion of resources devoted to transportation in Chapter 1 of Volume 1 also notes that resources equal to 9% of GDP were devoted to health care in Canada. Health and Welfare Canada has estimated that total public and private expenditures, on capital and operating costs of hospitals and other health care institutions, on physicians' and other health professionals' services, and on pharmaceuticals, equalled 8.7% of GDP in 1989 and 9.2% in 1990 (Policy, Planning and Information Branch, "Canadian Health Care Expenditures" by source of funds and by category, unpublished tables, March 1992). These appear to be conceptually comparable with the estimates of total resources devoted to transportation in Tables 1(2)-1 and 1(2)-2. Virtually all health care expenditures, however, would be classified as final expenditures in the National Income and Expenditure Accounts, unlike the case for transportation where, especially for freight transportation, a substantial portion would be classified as intermediate (an input into the production of other goods and services).

## 3. VALUE ADDED BY TRANSPORTATION CARRIERS

As noted, the estimate of total resources devoted to transportation presented in Table 1(2)-1 is a broad measure of the size of transportation in the economy. A very different measure, to which reference is more frequently made, is the "share of transportation industries in GDP." "Transportation industries," as defined by Statistics Canada, are basically the transportation carriers plus industries producing certain related services. The GDP of these industries is the value added by firms in the industries; that is, the value of their sales less the value of goods and services purchased from firms in other industries. This essentially represents the value of their wages, depreciation, interest and profits.

Table 1(2)-3 shows Statistics Canada data on GDP (at factor cost in constant 1986 dollars) in the transportation sector as percentages of total GDP (at factor cost in 1986 dollars). The percentage for total transportation, 4.8% in 1989, is much less than the Table 1(2)-2 estimate for total resources devoted to transportation. The difference reflects both the fact that the latter estimate included own account transportation activity by businesses, governments and, most importantly, consumers in the form of car travel, and the fact that it included total resources used including resources (for example, fuel) purchased from firms in other industries, as well as resources provided directly by transportation firms.

*Table 1(2)-3*

*GROSS DOMESTIC PRODUCT AT FACTOR COST FOR TRANSPORTATION INDUSTRIES, 1980–1989*

**a. Other transport industries include taxicab, other transportation, and highway and bridge maintenance industries. This component was calculated residually given the preceding components and the total for business sector industries.**

**b. Non-business sector industries include establishments, primarily government-owned, which provide services used by transportation carriers, including airport and port operation, and — where carried out by government departments — highway, street and bridge maintenance.**

**Note: Components may not add exactly to totals due to rounding.**

## 4. ESTIMATE OF RESOURCES DEVOTED TO INTERCITY PASSENGER TRANSPORTATION

Part A of Table 1(2)-4 shows estimates of the intercity passenger transportation share of the total carrier revenues in component I of Table 1(2)-1, and repeats from Table 1(2)-1 the allowance for use of company-owned aircraft — all of which is assumed to be for intercity passenger purposes. Also shown are two estimates of the intercity share of car use. These shares are intended to correspond to a broad definition of intercity car travel — (a) — all car travel on provincial highways, and a narrower definition — (b) — use of highways for trips extending beyond a single metropolitan or urban area.

The share corresponding to the broad definition (a) is defined using the ratio of estimated car vehicle-kilometres on provincial highways to total car vehicle-kilometres from Table 2(2)-A1, in the Annex to Notes to Chapter 2 in this volume. This ratio — 54.2% — is applied to total own account car expenditures (line 24) from Table 1(2)-1. The estimate for the narrower definition (b) is simply two thirds of the broad estimate — the same ratio as used in Notes to Chapter 2 in estimating car passenger-kilometres corresponding to the narrower definition of intercity travel.

Finally, Table 1(2)-4 includes an approximate allowance for the intercity passenger travel share of government transportation expenditures. For the purposes of this table, the estimate of relevant government transportation expenditures is defined using the ratio of non-government expenditures on intercity passenger travel (the sum of lines 5, 6 and 7 in Table 1(2)-4, or of lines 5, 6 and the value corresponding to line 7 for narrow intercity car use) to total non-government expenditures on transportation (the sum of lines 8, 14 and 24 in Table 1(2)-1). This ratio is applied to government capital and operating expenditures to support transportation net of government transportation charges (line 30 less line 35 from Table 1(2)-1).

A more painstaking, although still approximate, allocation of total government transportation expenditures to intercity passenger transportation was used to estimate government infrastructure costs for purposes of the modal cost comparisons in Chapter 3 of Volume 1 (further discussed in Notes to Chapter 3 in this Volume). However, to estimate an approximate overall share of resources devoted to intercity passenger transportation, the above procedure was considered adequate.

***Government capital and operating expenditures to support intercity passenger transportation net of transportation taxes/charges***

**Net government expenditures (i.e. line 30 to line 35 of Table 1(2)-1) times the ratio of intercity private expenditures from Table 1(2)-4 to total private expenditures from Table 1(2)-1. See text.**

Part B of Table 1(2)-4 shows the Part A dollar estimates expressed as percentages of GDP. The 1989 shares, rounded, are 5% for the narrower definition of intercity passenger transportation (b) and 7% for the broad definition (a). This is the basis for the percentages in Chapter 1.

An alternative broad estimate of total costs of domestic intercity passenger transportation may be obtained in Table 3-1(b) in Chapter 3. For 1991, this estimate — $43 billion — is 6.4% of GDP. The basis for this alternative estimate differs in a number of respects from that for the estimate in Table 1(2)-4. The alternative includes an estimate of environmental costs associated with intercity passenger transportation, but excludes the costs of international air travel. The alternative uses an annual stream of costs for capital used in transportation by consumers and governments, rather than expenditures on new capital in the year in question.

# INTRODUCTION

In describing the current situation of Canadian domestic intercity passenger transportation, and in briefly putting this situation in historical and international perspective, the text, charts and tables in Chapter 2 of Volume 1 present estimates for a number of aspects of passenger transportation, particularly when comparing the roles of the different means of transportation. In many cases, it is unfortunately not a question of simply reproducing data from official sources. Rather, Royal Commission staff have developed estimates for various aspects of passenger travel from a variety of sources. Development of the estimates often involves making assumptions that are based in part on judgement rather than solid evidence, and may involve a substantial element of approximation. The sections of these Notes to Chapter 2 are intended to set out the bases for the estimates used in Chapter 2, to report the estimates in fuller detail in a number of the cases, and to provide some additional discussion of conclusions to be drawn from the estimates.

Section 1 — Measures of the Shares of Different Means of Transportation in "Intercity Travel" — deals with the estimates of the current (1990) levels of Canadian domestic intercity passenger transportation provided by car, air, bus, train and ferry. The section refers briefly to charter/tour/cruise travel by bus and ship, which are not included in the basic estimates. Annex 1, at the end of these Notes to Chapter 2, provides a fuller explanation and reporting of estimates of total travel and total highway travel, by car.

Section 2 — Estimates of Domestic Intercity Passenger Transportation Modal Shares, 1930–1990 — explains the basis for, and comments on, the historical estimates of passenger-kilometres of domestic intercity travel by car, air, bus and rail for the period from 1930 to 1990.

Section 3 — International Comparisons of Modal Shares in Passenger Transportation — explains the basis for and comments on comparative estimates of distance travelled by car, airplane, bus and train for Canada, the United States, Japan, France, West Germany and the

United Kingdom. These estimates are for total domestic travel, not just domestic intercity travel, as reasonably comparable international information is only available for total domestic travel.

Sections 2 and 3 do not include travel by ferry. While it can be an important link in intercity travel, it generally accounts for only a fraction of 1% of total intercity distance travelled (passenger-kilometres).

Section 4 — Importance of Long and Short Trips in Domestic Intercity Travel — like Section 1, this section deals with current Canadian domestic intercity passenger transportation. It briefly presents some further information on the relative importance in total domestic travel of trips of different lengths.

## 1. MEASURES OF THE SHARES OF DIFFERENT MEANS OF TRANSPORTATION IN "INTERCITY TRAVEL"

Chapter 2 states that Canadians took over 150 million intercity trips in 1990, of which 134 million were in Canada. The chapter mentions the shares of trips and of total distance travelled for which the different means of passenger transportation account. This section provides a more detailed discussion of data on domestic intercity travel and describes the development of estimates of some aspects of intercity travel for which direct data are not available.

Information on the amount of intercity travel by the different means of passenger transportation helps provide a general understanding of the relative roles of the different means, of changes in these roles over time, and of differences across countries in the roles played by the different means. As is often the case with general descriptive statistics, however, a number of somewhat arbitrary choices have to be made regarding the basis on which to assemble the data. It is not always possible to find a single basis that is fully appropriate for the different purposes for which the statistics may be used. As well, basic data on some aspects of intercity travel, especially travel by car, are scarce. While estimates of total travel by each means are provided, in some cases the estimates are no more than informed guesses. They should be viewed as providing an indication of the broad picture, not as precise measures.

"Intercity" travel may be **defined** either in terms of characteristics of the trip, typically trips in excess of a specified length, or in terms of the means of travel used — air, train (or train other than specified commuter trains), intercity bus (as opposed to urban and suburban transit), specified types of ferries, and car travel involving specified classes of roads. The amount of intercity travel by any means of transportation can be **measured** in terms of number of trips, in terms of distance travelled (for example, passenger-kilometres), or conceivably in terms of total spending on travel by the means. With respect to both the definitions and the measures, it is often difficult to find an approach that treats the different means of transportation in a reasonably comparable manner.

There are further definitional issues to be resolved. Should travel include "cruise" or "tour" type trips? The main estimates generally exclude boat cruises, charter bus trips and "tourist trains"; in other words, the focus is on travel whose main purpose is to get from point A to point B. Supplementary information is provided, however, on some elements of cruise travel in subsection 1.5. If one is assembling data on domestic travel, which is the subject of this section, a further issue is the treatment of the domestic portion of international trips.

As discussed in the section entitled "A Data Detour" of *Getting There: The Interim Report of the Royal Commission on National Passenger Transportation* (pages 56–61), there are two basic sources of data on domestic travel in Canada: Statistics Canada's Canadian Travel Survey (CTS), which asks a sample of Canadians about the intercity trips they have taken over the previous three months, and data reported by carriers on passengers carried. For travel by car, the CTS provides some data, but car data that correspond directly to the carrier data for the public means of travel do not exist. For private car use, information on volume of traffic on highways or, failing that, on fuel consumption and on motor vehicle registrations provides a partial parallel to the carrier data for the public means of passenger transportation.

The CTS provides an estimate of domestic (and international) trips taken in excess of 80 kilometres in one-way distance. The trip is identified by the primary means used. Thus, as noted in the Interim Report, a trip from Victoria to Kingston that involves travel by bus and ferry from Victoria to Vancouver, by airplane from Vancouver to Toronto, and by train from Toronto to Kingston would be recorded as one air trip. Estimates are provided of both numbers of trips and total passenger-kilometres travelled.

The estimates of total travel by the different means of transportation are certainly of interest, but they give an incomplete view of intercity travel in Canada for a number of reasons:

- As illustrated by the Victoria to Kingston example, information on the role of any secondary modes used in the course of a trip is not provided.
- Travel within Canada by residents of other countries is not included.
- Respondents to the CTS may fail to recall some trips, especially shorter car and bus trips.
- Finally, information on trips under 80 kilometres in length would be useful for some purposes. Such trips likely account for a significant portion of the business of the ferry and intercity bus industries, some of the business of the passenger rail industry, and a substantial portion of use of highways by cars.

Table 2(2)-1, which is an update of Table III-1 of the Royal Commission's Interim Report, shows 1990 estimates of domestic intercity trips or of passengers carried, and of passenger-kilometres travelled, from the Canadian Travel Survey and from carrier data or other sources. As indicated earlier, the carrier data, and the alternative car passenger-kilometre estimate, are more inclusive. They are attempts to measure all domestic travel excluding travel within a single urban or metropolitan area and short car trips on secondary rural roads.

*Table 2(2)-1*

*INFORMATION ON DOMESTIC INTERCITY TRAVEL (FROM ALTERNATIVE SOURCES, 1990)*

| | Car | Air | Intercity bus | Rail (excluding commuters) | Intercity ferries | Total |

[a] **This figure is slightly less than twice the estimate of 134 million domestic round trips referred to in Chapter 2. The latter figure includes travel by other and unspecified means.**

## 1.1 CANADIAN TRAVEL SURVEY ESTIMATES OF TRIPS AND PASSENGER-KILOMETRES

CTS-based estimates of trips are the CTS survey figures for round trips (Statistics Canada, Catalogue No. 87-504) multiplied by two to obtain one-way equivalent figures for comparison with the carrier-based estimates of passengers carried. The CTS-based estimate of passenger-kilometres is taken from unpublished CTS survey results.

## 1.2 CARRIER-BASED ESTIMATES — PASSENGERS CARRIED

### 1.2.1 Air

Statistics Canada, *Air Passenger Origin and Destination, Domestic Report 1990,* Catalogue No. 51-204, August 1991, Table 3, reports 13 million domestic origin-destination (O-D) trips in 1990. This report, based on data from the "Scheduled Air Passenger O-D Survey," records the total number of trips flown between city-pairs on a subset of large domestic carriers. Since it only includes passenger trips on the scheduled services of nine major airlines, the report underestimates the number of total trips. Data on domestic charter activity and O-D trips entirely on smaller airlines should also be considered.

Statistics Canada, *Air Charter Statistics 1990,* Catalogue No. 51-207 reports that in 1990 almost 330,000 trips were taken aboard domestic charters.

In addition, Statistics Canada's unpublished "System Passenger Origin and Destination Survey" showed that in 1990 almost 3 million O-D trips were taken on the smaller regional and local air carriers in Canada. Only a portion of these trips, however, can be considered as additional trips since many of these smaller airlines interline with the carriers counted by the "Scheduled Air Passenger O-D Survey." In an interline arrangement, passengers from one carrier transfer to another carrier and continue their journey. For example, a passenger flying First Air from Iqaluit, N.W.T., to Ottawa then transferring to Air Canada in Ottawa and continuing to Toronto would be counted as a Scheduled O-D Survey passenger from Iqaluit to Toronto because the itinerary includes a flight stage aboard Air Canada's system. A passenger flying First Air from Iqaluit to Yellowknife would not appear in the Scheduled Air Passenger O-D Survey but would be counted by the System O-D Survey, which measures the scheduled O-D traffic within route systems of all Levels 2 to 5 airlines. There are no data on how many trips recorded by the Scheduled Air Passenger O-D Survey involve smaller carriers. Following the approach of an unpublished

Statistics Canada study, one quarter of the System O-D trips for carriers not included in the Scheduled O-D Survey are counted as separate trips. This amounted to over 700,000 trips in 1990.

Adding the domestic charter O-D trips and the allowance for trips on smaller carriers to the reported 13 million O-D trips yields an overall estimate of 14.1 million trips.

### 1.2.2 Intercity Bus

Bus trips for 1990 were estimated by reducing the 1989 passenger level for the intercity passenger bus industry (Statistics Canada, *Passenger Bus and Urban Transit Statistics*, Catalogue No. 53-215) by 7%, the average annual rate at which passengers carried fell between 1984 and 1989. This results in an estimate of 16 million passengers. In addition, bus operators classified as school bus operators, and as charter and sightseeing bus operators also offer some scheduled intercity bus services. Unfortunately, only vehicle-kilometres are recorded for these firms. In order to derive an estimate of passengers carried by these firms, an assumed occupancy rate of 21 passengers per bus was used. Secondly, passengers were assumed to have an average trip length of 100 km — half that estimated for the intercity passenger bus industry. This yields an estimate of 2 million passengers carried on other scheduled services or 14% of the intercity bus industry figure. The overall estimate of intercity bus passengers is 18.2 million.

### 1.2.3 Rail

The rail passengers figure is the sum of VIA Rail passengers (Statistics Canada, *Rail in Canada 1990*, Catalogue No. 52-216, Figure 3.10), and unpublished statistics for other intercity railways. Commuter services are excluded. In 1990, about 3.8 million passengers were carried, a significant reduction from 1988, reflecting the elimination of about half of the VIA Rail network.

### 1.2.4 Intercity Ferries

Intercity ferry passengers carried include all domestic passengers on BC Ferries, Marine Atlantic, Northumberland Ferries, other Atlantic region ferries, Ontario Northland, and the longer St. Lawrence River crossings, primarily those of the Société des Traversiers du Québec. Data were obtained either from annual reports or directly from the carriers. In 1990, these services together transported about 23.5 million passengers.

## 1.3 CARRIER-BASED ESTIMATES — PASSENGER-KILOMETRES

### 1.3.1 Air

Domestic air passenger-kilometres are taken from Statistics Canada, *Canadian Civil Aviation 1990*, Catalogue No. 51-206, November 1991, Table 2.2. Data include both scheduled and charter domestic passenger-kilometres of Levels 1 to 4.

### 1.3.2 Intercity Bus

The bus passenger-kilometres figure is an estimate derived using 1989 data on bus-kilometres for intercity passenger bus operators and for other passenger bus operators that offer scheduled intercity services (for example, school bus, and charter and sightseeing establishments), together with an assumed average occupancy rate (passengers per bus). In 1989, intercity services produced almost 170 million bus-kilometres. Assuming an occupancy of 21 passengers per bus,[1] yields an estimate of over 3.5 billion passenger-kilometres. Bus passenger-kilometres have been falling steadily at about 3% per annum since the mid-1980s; the estimate for 1990 is thus about 3.4 billion passenger-kilometres.

### 1.3.3 Rail

The rail passenger-kilometres figure is the sum of statistics for VIA Rail (Statistics Canada, *Rail in Canada 1990*, Catalogue No. 52-216, Figure 3.10) and unpublished data on the other intercity railways.

Commuter services are again excluded. In 1990, about 1.4 billion passenger-kilometres were recorded, a significant reduction from 1988.

### 1.3.4 Intercity Ferries

Ferry passenger-kilometres are calculated using the number of passengers carried on each route and an estimate of the average distance sailed on the route. This yields an estimate for 1990 of about 0.8 billion passenger-kilometres.

## 1.4 ALTERNATIVE ESTIMATE OF CAR PASSENGER-KILOMETRES

The estimate is simply two thirds of the Royal Commission staff estimate of 205 billion passenger-kilometres for total car travel on highways (including use of small vans and light trucks for passenger transportation purposes). The basis for the total highway travel estimate is described in Annex 1. The estimate of total car travel on highways is itself subject to a considerable range of uncertainty, particularly in the assumption as to the average number of people occupying a car during highway travel. Multiplication by the two-thirds factor makes a very rough allowance for the fact that provincial highways that pass through metropolitan areas are often heavily used for urban travel. Thus, a considerable fraction of total highway use consists of trips that are not intercity but are entirely within metropolitan areas.

The carrier and alternative car estimates are considerably higher than the CTS estimates for all modes except air. Because they give a more complete — although in some cases very approximate — view of the role of the different modes, they receive primary emphasis in most of the following sections of these Notes to Chapter 2.

The 70% estimate from the CTS of the share of the car in intercity passenger-kilometres should be considered a minimum estimate. It seems very likely that a larger fraction of car trips than of trips by other modes, especially air, are missed from the survey due to failure of the respondent to recall all trips taken. Further, as noted earlier, for some purposes there is interest in trips under 80 kilometres in one-way distance, of which the car would be expected to have an overwhelming share, followed by bus. The rough alternative estimates of intercity car passenger-kilometres, when combined with the other carrier-based estimates, result in a car share of 82%. The very approximate nature of the allowance for the intercity share of total highway travel is reflected in the reference in the section "How Canadians Travel," in Chapter 2 of Volume 1, to car travel as accounting for "around 80 percent of all domestic intercity passenger-kilometres travelled in Canada."

## 1.5 TOUR/CRUISE TRAVEL

As noted, Table 2(2)-1 is intended to cover intercity travel, rather than specialized sightseeing tours or cruises. In part this is because sightseeing tours do not generally provide an effective alternative for people whose main objective is to travel from point A to point B. Some bus group charters, however, may be a substitute for use of public carriers. Data on numbers of tour/cruise passengers and passenger-kilometres tend to be even sketchier than other travel data.

The "carrier-based," and presumably the "CTS-based," estimates in Table 2(2)-1 do include domestic air travel by "charter services" — where charter in this case refers to aircraft operators who sell individual seats in an aircraft flying at times specified by the operator. (The table does not include air travel on small chartered aircraft where the aircraft itself is chartered to take the travellers to a destination on a schedule specified by the travellers.)

The carrier-based estimates in Table 2(2)-1 include little if any travel by "tour trains." Until recently, tour trains have generally been confined to short day trips, but with the Rocky Mountaineer service, and potentially other services in the future, this type of train travel may become more important.

The bus and boat estimates are more substantially affected by the treatment of charter/tour/cruise travel. Some charter/tour/cruise travel by bus and boat is presumably included in the CTS-based estimates (the "ferries" heading should read "boat" as far as the CTS estimates are concerned). For bus, as shown later, the number of bus-kilometres of service provided by operators that specialize in charter services is more than one third the level of bus-kilometres in intercity service by intercity bus operators. As charter services almost certainly operate with higher average occupancy rates, in passenger-kilometre terms they may well equal half or more of the scheduled intercity level. The table shows a set of estimates of non-urban charter activity, together with the assumptions on which the estimates are based.

With about 200,000 passengers,[2] cruise ship operations in Canadian waters may well generate revenues of the same order as intercity ferry operations ($300 million a year). The number of cruise passengers is divided about 90% west coast and 10% inland and east coast. The cruise industry includes excursion boats, with no overnight accommodation, and cruise ships. The passenger and rough revenue estimates given earlier, however, do not include day excursion operations.

Cruise, as opposed to excursion, ships are mainly foreign registered (foreign flag), built and crewed. Most of them are operated by foreign companies although some may be under charter to Canadian companies. The Canadian registered ships are the smaller ones and generally sail on the Great Lakes, St. Lawrence and east coast. Recent changes to legislation permit foreign registered ships above 250 berths to engage in international cruise service but reserve to Canadian registry service by vessels of 250 berths or less.

*Table 2(2)-2*

*INTERCITY SCHEDULED AND CHARTER BUS PASSENGER-KILOMETRES ESTIMATE, 1989*

*(MILLIONS)*

| Operator | Intercity scheduled service | | Charter (non-urban)[a] | |
|---|---|---|---|---|
| | bus-km | pass-km[b] | bus-km | pass-km[c] |
| Intercity bus class 1 and 2 | 156 | 3,276 | 20[d] | 692 |
| Other passenger bus[e] | 6 | 126 | 49 | 1,711 |
| School bus[e] | 5 | 105 | [f] | |
| Intercity bus class 3[g] | 2 | 42 | | |
| **Total** | **169** | **3,549[h]** | **69** | **2,403** |

**Source: Derived from data from Statistics Canada, *Passenger Bus and Urban Transit Statistics*, Catalogue No. 53-215, 1989.**

**a. The charter total is reduced by 25% as a rough allowance for local (urban) activity.**

**b. Assuming an average load of 21 passengers.**

**c. Assuming an average load of 35 passengers.**

**d. Calculated from the proportion of charter revenues to unit toll revenues.**

**e. School busing not included.**

**f. Although school bus charters do on occasion range beyond the 80 km threshold, this class of operators has been excluded as constituting primarily local activity.**

**g. Estimated from 1988 data (Class 3 data were dropped in 1989).**

**h. This figure, reduced by the recent average annual rate of decrease, is the basis for the estimate of 1990 intercity bus passenger-kilometres in Table 2(2)-1.**

## 2. ESTIMATES OF DOMESTIC INTERCITY PASSENGER TRANSPORTATION MODAL SHARES, 1930–1990

Chart 2-5, in Chapter 2, shows rough estimates of the car, bus, rail and air shares, measured in passenger-kilometres, of Canadian intercity transportation over the last 60 years. As discussed in Section 1 of Notes to Chapter 2, the estimate of passenger-kilometres of intercity travel by car is very rough. The widest margins of uncertainty arise due to lack of good information on the average number of persons occupying cars when they are used for intercity travel, and on the fraction of car travel on highways that is intercity in nature. The estimate of passenger-kilometres of intercity travel by bus is also subject to significant uncertainty. Thus Chart 2-5 and the tables in this section only provide a very general indication of past trends — not precise estimates.

## 2.1 BASIS FOR ESTIMATES

As will be set out in more detail later, reasonably good data on air and rail passenger-kilometres of travel exist for most or all of the historical period under consideration. For car and bus, however, there are no data that directly measure travel. In these latter cases, the extrapolation backwards from the present is based on other statistical series, such as fuel consumption, which shed some light on the way the total amount of travel by these means has changed over time.

### 2.1.1 Car

The very approximate backwards extrapolation of the level of intercity car travel in effect makes use of historical data on gasoline sales, estimates of the fraction used in cars, and estimates of average fuel economy, to produce estimates of changes in car vehicle-kilometres. Then, multiplying by an index of assumed occupancy rates provides estimates of changes in passenger-kilometres of travel. The derivation of the estimates for passenger automobiles is set out in more detail later. Component historical series used are shown in Table 2(2)-3. (The explanation is organized in terms of the columns in the table.)

1. Data on sales of gasoline in Canada taxed for use by road motor vehicles are available for the full period covered. For the period 1977 to 1989, however, the source data do not include gasoline sales in Alberta and/or Saskatchewan for years in which no gasoline taxes were levied. The series shown in the table, however, has been adjusted to include an approximate allowance for sales in these provinces over the periods in which taxes were not levied.
2. In the absence of extended Canadian historical data series on the fraction of gasoline sales for use in automobiles, it is assumed that the Canadian fraction changed in proportion to the corresponding fraction for the United States. Data on total gasoline sales for road motor vehicles, and for automobiles, for the United States are available from 1948 to 1990. As well, closely related data are available for earlier years; this allows an approximate series to be produced for the years prior to 1948.

*Table 2(2)-3*

### SERIES USED TO EXTRAPOLATE BACKWARDS THE 1990 ESTIMATE OF AUTOMOBILE PASSENGER-KILOMETRES

| Year | (1) Net sales of gasoline for road motor vehicles — Canada (billions of litres) | (2) Auto gasoline sales as share of road gasoline sales — U.S. (%) | (3) Auto fuel efficiency — U.S. (litres/ 100 km/per vehicle) | (4) Index of vehicle-kilometres ((1 × 2) ÷ 3) (1990= 100) | (5) Population per registered auto — Canada (persons per car) | (6) Index of occupancy rate — Canada (1990= 100) | (7) Index of passenger-kilometres (4 × 6) (1990= 100) |
|---|---|---|---|---|---|---|---|
| 1930 | 2.1 | 77.2 | 15.4 | 5.7 | 9.6 | 148.3 | 8.4 |
| 1932 | 2.1 | 76.7 | 15.4 | 5.6 | 11.1 | 148.3 | 8.3 |
| 1934 | 2.2 | 76.2 | 15.4 | 5.8 | 11.2 | 149.7 | 8.6 |
| 1936 | 2.4 | 75.7 | 15.4 | 6.4 | 10.5 | 149.0 | 9.5 |
| 1938 | 2.9 | 75.1 | 15.4 | 7.5 | 9.6 | 148.3 | 11.2 |
| 1940 | 3.2 | 74.6 | 15.4 | 8.3 | 9.2 | 147.0 | 12.2 |
| 1942 | 2.8 | 72.9 | 15.5 | 7.0 | 9.6 | 146.3 | 10.3 |
| 1944 | 2.6 | 68.2 | 15.7 | 6.1 | 10.1 | 147.0 | 9.0 |
| 1946 | 4.5 | 73.8 | 15.8 | 11.5 | 10.0 | 147.7 | 16.9 |
| 1948 | 5.2 | 71.0 | 15.8 | 12.5 | 8.6 | 145.6 | 18.2 |
| 1950 | 6.3 | 69.1 | 15.8 | 14.9 | 7.2 | 143.6 | 21.4 |
| 1952 | 7.8 | 70.3 | 16.1 | 18.4 | 6.3 | 140.3 | 25.8 |
| 1954 | 9.2 | 71.3 | 16.2 | 21.8 | 5.6 | 138.3 | 30.2 |
| 1956 | 11.2 | 72.3 | 16.4 | 26.5 | 5.0 | 136.2 | 36.1 |
| 1958 | 12.4 | 73.8 | 16.5 | 30.0 | 4.7 | 134.2 | 40.2 |
| 1960 | 13.7 | 74.2 | 16.5 | 33.2 | 4.4 | 132.9 | 44.1 |
| 1962 | 14.8 | 74.4 | 16.4 | 36.2 | 4.1 | 131.5 | 47.6 |
| 1964 | 16.8 | 74.0 | 16.5 | 40.5 | 3.8 | 129.5 | 52.4 |
| 1966 | 19.4 | 78.5 | 16.7 | 49.3 | 3.7 | 127.5 | 62.8 |
| 1968 | 21.6 | 79.1 | 17.0 | 54.4 | 3.4 | 125.5 | 68.2 |
| 1970 | 24.1 | 79.2 | 17.4 | 59.1 | 3.2 | 122.8 | 72.5 |
| 1972 | 26.9 | 79.0 | 17.6 | 65.2 | 2.9 | 120.1 | 78.4 |
| 1974 | 30.3 | 77.8 | 17.5 | 72.5 | 2.6 | 116.8 | 84.6 |
| 1976 | 32.4 | 75.9 | 17.4 | 76.3 | 2.6 | 112.8 | 86.0 |
| 1978 | 34.7 | 72.8 | 16.8 | 81.2 | 2.4 | 109.4 | 88.8 |
| 1980 | 35.7 | 71.0 | 15.2 | 89.9 | 2.3 | 107.4 | 96.5 |
| 1982 | 31.2 | 71.1 | 14.1 | 84.6 | 2.3 | 106.0 | 89.7 |
| 1984 | 30.4 | 67.8 | 13.2 | 84.0 | 2.3 | 104.0 | 87.3 |
| 1986 | 30.5 | 66.7 | 12.9 | 85.2 | 2.2 | 104.0 | 88.6 |
| 1988 | 32.1 | 65.5 | 11.8 | 95.6 | 2.1 | 102.0 | 97.5 |
| 1990 | 31.8 | 65.7 | 11.2 | 100.0 | 2.1 | 100.0 | 100.0 |

3. In the absence of extended Canadian historical data series on average fuel economy for passenger automobiles, it is also assumed that average fuel economy in Canada varied in line with fuel economy in the United States. Data were available from 1936 to 1990 for the United States; the 1936 value was assumed to apply from 1930 to 1935.

   In deriving an estimate of the change over time in intercity vehicle-kilometres, it would be desirable also to allow for any change in the intercity share of total car travel. There are no directly relevant data for Canada or the United States. U.S. data, however, show an approximately constant share for vehicle-miles on interstate highways and main rural roads relative to total automobile vehicle-miles. The estimate makes no allowance for any possible change in the share of intercity driving in total car travel.

4. Column 4 is the product of columns 1 and 2, divided by column 3, and indexed to 1990. It shows automobile vehicle-kilometres over this period.

5. and 6.

   There is also little direct information on average occupancy, but there is reason to believe that the average occupancy rate has fallen as car ownership has become more widespread. Canadian data do exist on the ratio of car passengers to car drivers killed in car accidents for the period 1942 to the present. This ratio has declined fairly steadily since 1942, suggesting that the average occupancy ratio has also declined. While the ratio of car occupant fatalities to car driver fatalities is not necessarily a good indicator of the average level of car occupancy, it seems reasonable to assume that, over time, these two series would tend to move in step. The automobile passenger-kilometre estimates assume that, over the historical period, the occupancy rate maintained a constant proportionate relation to the ratio of total passenger and driver fatalities to driver fatalities. A simple statistical relation between the occupancy rate from car fatalities and the ratio of population to registered automobiles was estimated for the period from 1942 to 1990. Together with information on the ratio of population to registered automobiles for the full historical period (column 5), this was used to create an occupancy index (column 6) for the full historical period.

7. Multiplying the index of vehicle-kilometres (column 4) by the index of occupancy rates provides an overall index of automobile passenger-kilometres. Given the further assumption of no change in the ratio of intercity automobile travel to total automobile travel, this is also an index of intercity passenger-kilometres. Column 7 shows this overall index with 1990 = 100 as the base value.

The overall index in column 7 is used to extrapolate backwards from the estimated level of intercity automobile travel for 1990 (Annex 1) to produce the very rough historical estimates of intercity automobile passenger-kilometres in Table 2(2)-5. A parallel approach is used to extrapolate backwards from the 1990 estimate of intercity passenger travel in light trucks. Again, U.S. data are used to provide indexes of changes in the share of gasoline consumed by light trucks, and of changes in light-truck fuel economy. A number of additional adjustments were made to the published U.S. historical series to produce the estimate for light trucks shown in Table 2(2)-5.

### 2.1.2 Bus

Intercity bus passenger-kilometres were extrapolated backwards from 1990 using the series shown in Table 2(2)-4.

Table 2(2)-4

## SERIES USED TO EXTRAPOLATE BACKWARDS THE 1990 ESTIMATE OF INTERCITY BUS PASSENGER-KILOMETRES

| Year | (1) Bus-km (millions) | (2) Average bus capacity (seats) | (3) Index of bus pass-km (1990=100) |
|---|---|---|---|
| 1930 | | | 8.1 |
| 1932 | | | 6.9 |
| 1934 | | | 7.5 |
| 1936 | | | 10.3 |
| 1938 | | | 9.4 |
| 1940 | | | 16.9 |
| 1942 | 82.4 | 24.6 | 31.7 |
| 1944 | 84.3 | 24.9 | 32.8 |
| 1946 | 136.9 | 26.9 | 57.6 |
| 1948 | 173.3 | 29.1 | 78.9 |
| 1950 | 168.2 | 29.4 | 77.3 |
| 1952 | 165.7 | 30.3 | 78.4 |
| 1954 | 150.4 | 31.2 | 73.2 |
| 1956 | 142.7 | 32.7 | 72.9 |
| 1958 | 130.2 | 34.3 | 69.7 |
| 1960 | 137.9 | 34.9 | 75.2 |
| 1962 | 142.6 | 36.3 | 80.9 |
| 1964 | 148.0 | 36.8 | 85.0 |
| 1966 | 170.3 | 38.1 | 101.4 |
| 1968 | 177.7 | 38.7 | 107.4 |
| 1970 | 173.3 | 39.3 | 106.3 |
| 1972 | 172.7 | 39.5 | 106.7 |
| 1974 | 172.1 | 39.8 | 107.1 |
| 1976 | 181.4 | 40.1 | 113.7 |
| 1978 | 189.7 | 40.4 | 119.7 |
| 1980 | 201.5 | 40.7 | 128.1 |
| 1982 | 196.0 | 41.0 | 125.4 |
| 1984 | 180.3 | 41.3 | 116.2 |
| 1986 | 172.2 | 41.6 | 111.8 |
| 1988 | 156.8 | 41.9 | 102.5 |
| 1990 | 152.4 | 42.0 | 100.0 |

**Sources:** ***Bus-km and capacity to 1970*****: 1941–1955: Dominion Bureau of Statistics, *Motor Carriers — Freight — Passenger*, Catalogue No. 53-D-20. 1956–1970: Statistics Canada, *Passenger Bus Statistics*, Catalogue No. 53-215. 1974–1989: Statistics Canada, *Passenger Bus and Urban Transit Statistics*, Catalogue No. 53-215.**

**Notes:** **Index for 1930–1940 based on linkage to statistics compiled by Gordon D. Campbell, "An Analysis of Highway Finance and Road User Imposts in Canada," (Ph.D. thesis, Purdue University, 1956), Table 32, p. 258.**

**A constant load factor of 50% of average capacity was assumed throughout the period.**

1. Published data on vehicle-kilometres by buses operated by the intercity bus industry were available for the period 1941 to 1990. Data are available for bus operators with annual revenues in excess of $20,000 for years up to 1970 and for bus operators with annual revenues in excess of $100,000 for 1974 and later years.

   These two series were used without adjustment, in spite of the reduction in coverage at the time of the shift from $20,000 to $100,000 and in spite of the tendency to relative underestimation for the earlier years in each series. Due to inflation, the exclusion of operators with revenues under $20,000 or $100,000 presumably involves the exclusion of relatively more, and relatively larger, operators in the early years of the series than in the later years. As data were not published for 1972, the figure for that year is the average of the 1970 and 1974 values.

   No allowance is made for any possible change in the relative importance of scheduled intercity bus service provided by school and charter bus operators not classified in the intercity bus industry. As indicated in Section 1 of these Notes to Chapter 2, in 1990 such operators were estimated to provide 7% of total intercity bus passenger-kilometres.

2. The size of the average bus has tended to become larger over the historical period. Column 2 shows a rough estimate of the average size of intercity buses in use. This was derived from information on the number of buses by number of seats, which is available for certain years over the period.

3. The index of changes in the amount of bus travel (column 3) is the product of columns 1 and 2, with 1990 = 100 as the base. It is assumed that average occupancy as a percent of seating capacity has remained constant over the period (50%).

For the years from 1930 to 1940, for which there are no published data on intercity bus vehicle-kilometres, the index has been extrapolated backwards from 1941 on the basis of estimates of intercity bus passenger-kilometres in a study by Gordon Campbell.[3]

The resulting index for 1930 to 1990 is applied to the 1990 estimate of intercity bus passenger-kilometres (Table 2(2)-1) to produce the rough historical estimate of intercity bus passenger-kilometres in Table 2(2)-5.

### 2.1.3 Air

Published passenger-kilometre data are available for domestic scheduled air services for the years 1936 to 1990. These data were adjusted by adding an estimate of passenger-kilometres on domestic charter services to produce the series in Table 2(2)-5. Estimated passenger-kilometres on domestic charter services were equal to 8%, on average, of total domestic passenger-kilometres from 1964 to 1990.

Published data on total passenger-kilometres provided by Canadian air carriers are available for 1930 to 1935; the domestic portion was assumed to be equal to 85% for this period based on the portion in the immediately following years.

### 2.1.4 Rail

Published data exist on total rail passenger-kilometres back to 1910. Unpublished data from Statistics Canada on passenger-kilometres on commuter services from 1970 onwards were used to produce estimates of intercity rail passenger-kilometres. The commuter share pre-1970 was assumed to equal the 9% average share of the early 1970s.

## 2.2 SUMMARY TABLES ON INTERCITY PASSENGER TRAVEL

The estimates of passenger-kilometres of domestic intercity travel by the different means of intercity passenger transportation, derived as discussed earlier, are presented in Table 2(2)-5. The next three tables present the same information in alternative forms to facilitate various types of analysis. Table 2(2)-6 shows the average annual growth rates for the series by decade and for certain longer intervals. Table 2(2)-7 expresses the estimates as percentage shares of total domestic intercity travel; these percentage shares are also displayed in Chart 2-5 of Chapter 2, Volume 1. Table 2(2)-8 presents the estimates in terms of passenger-kilometres of travel per capita. This per capita table is intended to provide an impression of changes in amount of travel abstracting from overall growth in population. The per capita figures — that is, the estimates of total amounts of domestic intercity travel in Table 2(2)-5 divided by total population — obviously are not estimates of total annual travel or the change in total annual travel, by the average **user** of the mode in question. Only a fraction of the population uses any given mode and this fraction has almost certainly changed substantially over the historical period considered, although there are few direct data on this point. The fraction of the population using the air mode in a year will have risen very substantially. The fraction using cars for intercity travel probably rose somewhat, especially over the first three or four decades of the period; the fraction using intercity rail has almost certainly declined substantially since World War II; and the fraction using intercity bus may well have declined since the 1950s.

Given the very rough nature of the estimates of intercity travel by car and bus, the tables only serve to provide a general sense of the trends in intercity travel over time. They do, however, provide an adequate basis for the following general observations:

- Car travel already accounted for a large share of intercity travel by the 1930s. The absolute amount of car travel, and even more so its share of total travel, fell during World War II. Presumably this was primarily a result of the rationing of gasoline and the fact that the government used rail and bus for very large movements of military personnel. Car rapidly returned to a dominant position after the war, and its share appears to have been relatively stable since — possibly increasing modestly into the 1960s and then declining modestly over the last two decades as air travel has increased dramatically.

Table 2(2)-5

## DOMESTIC INTERCITY TRAVEL IN CANADA, 1930–1990

(BILLIONS OF PASSENGER-KILOMETRES)

| Year | "Car" | | | Sched./ charter air | Intercity rail | Intercity bus | Total intercity travel |
|---|---|---|---|---|---|---|---|
| | Total | Auto. | Light trucks/ vans | | | | |
| 1930 | 10.2 | 9.7 | 0.5 | 0.007 | 3.3 | 0.4 | 13.9 |
| 1932 | 10.1 | 9.6 | 0.5 | 0.004 | 2.0 | 0.3 | 12.4 |
| 1934 | 10.5 | 10.0 | 0.5 | 0.009 | 2.1 | 0.3 | 13.0 |
| 1936 | 11.7 | 11.1 | 0.6 | 0.012 | 2.4 | 0.5 | 14.5 |
| 1938 | 13.7 | 13.0 | 0.7 | 0.014 | 2.4 | 0.4 | 16.5 |
| 1940 | 15.0 | 14.2 | 0.8 | 0.059 | 3.0 | 0.8 | 18.8 |
| 1942 | 12.6 | 11.9 | 0.7 | 0.104 | 6.8 | 1.1 | 20.6 |
| 1944 | 11.2 | 10.4 | 0.8 | 0.2 | 9.4 | 1.1 | 21.9 |
| 1946 | 20.8 | 19.6 | 1.2 | 0.3 | 6.4 | 2.0 | 29.3 |
| 1948 | 22.5 | 21.1 | 1.5 | 0.4 | 4.8 | 2.7 | 30.4 |
| 1950 | 26.7 | 24.9 | 1.9 | 0.6 | 3.8 | 2.6 | 33.8 |
| 1952 | 32.1 | 29.9 | 2.2 | 0.9 | 4.3 | 2.7 | 40.0 |
| 1954 | 37.5 | 34.9 | 2.6 | 1.2 | 3.9 | 2.5 | 45.1 |
| 1956 | 44.9 | 41.8 | 3.0 | 1.6 | 4.0 | 2.5 | 52.9 |
| 1958 | 49.8 | 46.6 | 3.2 | 2.0 | 3.4 | 2.4 | 57.5 |
| 1960 | 54.7 | 51.1 | 3.6 | 2.7 | 3.1 | 2.6 | 63.0 |
| 1962 | 59.0 | 55.2 | 3.9 | 3.4 | 2.8 | 2.8 | 68.0 |
| 1964 | 65.7 | 60.8 | 5.0 | 3.7 | 3.7 | 2.9 | 76.0 |
| 1966 | 77.4 | 72.8 | 4.6 | 5.1 | 3.5 | 3.4 | 89.5 |
| 1968 | 84.2 | 79.1 | 5.1 | 6.5 | 3.5 | 3.7 | 97.8 |
| 1970 | 90.1 | 84.1 | 6.0 | 8.8 | 3.1 | 3.6 | 105.7 |
| 1972 | 98.3 | 90.9 | 7.5 | 9.9 | 2.8 | 3.6 | 114.6 |
| 1974 | 107.6 | 98.1 | 9.5 | 13.9 | 2.5 | 3.6 | 127.6 |
| 1976 | 110.8 | 99.7 | 11.2 | 14.5 | 2.4 | 3.9 | 131.6 |
| 1978 | 116.3 | 102.9 | 13.4 | 16.3 | 2.5 | 4.1 | 139.2 |
| 1980 | 127.5 | 111.9 | 15.7 | 21.0 | 2.7 | 4.4 | 155.5 |
| 1982 | 118.5 | 103.9 | 14.6 | 18.9 | 2.1 | 4.3 | 143.8 |

**Source:** Table 2(2)-5.

- Rail was the dominant intercity public carrier in the 1930s, although it was almost certainly much less important than private use of car even then. During World War II, rail's share may have approached the share of the car, but by the 1950s rail's share was almost certainly below its share in the 1930s, and by the 1960s air had overtaken rail as the public carrier with the largest share of domestic passenger-kilometres. Rail's share fell below that of intercity bus by the 1970s, and has continued to decline with a further sharp drop in 1990 reflecting the reductions in VIA Rail routes. The level of rail passenger-kilometres has shown a declining trend throughout the post-war period.

- Domestic intercity travel by air has grown in a manner typical of a successful new technology (or series of new technologies). It showed high growth rates from a very small base in the early decades and growth rates only moderately higher than the growth of intercity travel as a whole in the most recent period.

- Abstracting from the bulge in domestic intercity bus travel during the special conditions of World War II, the bus share in domestic intercity travel appears to have increased substantially from the 1930s to around 1950. The share has subsequently displayed a downward trend, although the rate of decline has been more gradual than for the rail share. For the 1950s through the 1970s, the decline in the bus share reflected slower growth in travel by intercity bus than in total intercity travel, rather than an absolute decline in the amount of bus travel. During the 1980s, however, there was a decline in total bus passenger-kilometres.

- The total and per capita amounts of domestic intercity travel, taking all modes together, have increased very substantially over the last 60 years — more than quadrupling in per capita terms according to the estimates used here. The increase in per capita travel, however, appears to have slowed markedly in recent years.

## 2.3 EARLIER ESTIMATE OF HISTORICAL TRENDS IN INTERCITY PASSENGER-KILOMETRE SHARES

A set of reasonably comprehensive estimates of intercity modal shares is contained in *Canadian Transportation Economics* by A. W. Currie, published in 1967. These estimates apparently apply to a definition of intercity travel that is similar to that which underlies the estimates presented in these Notes. Little detail on methodology or data sources is provided. Table 2(2)-9 compares Currie's estimates of intercity modal shares with those in Table 2(2)-7.

*Table 2(2)-9*

*Comparison of Estimates of Historical Modal Shares in Domestic Intercity Travel (Passenger-Kilometres)*

|  | Currie | Table 2(2)-7 | Currie | Table 2(2)-7 | Currie | Table 2(2)-7 | Currie | Table 2(2)-7 |
|---|---|---|---|---|---|---|---|---|
| **Year** | **1928** | **1930** | **1951** | **1952** | **1957** | **1958** | **1964** | **1964** |
| Car | 60 | 73 | 72 | 80 | 83 | 86 | 85 | 86 |
| Airplane | — | — | 3 | 2 | 4 | 4 | 5 | 5 |
| Bus | 2 | 3 | 11 | 7 | 5 | 4 | 5 | 4 |
| Train | 38 | 24 | 15 | 11 | 8 | 6 | 5 | 5 |

**Sources: A.W. Currie, *Canadian Transportation Economics* (Toronto: University of Toronto Press, 1967), p. 299 and Table 2(2)-7.**

The two sets of estimates show broadly similar trends, although Currie does estimate a smaller share for car and a higher share for rail, with the differences relative to the estimates developed here diminishing from the 1930s through the 1960s. Given the lack of information on Currie's assumptions, it is not possible to identify the source of the differences. It is possible that the assumption used here, that the intercity share in total car travel was approximately constant over the period at the 1990 level, results in an upward bias in the estimates of the car share for the earlier part of the period. This assumption does receive some support from the fact that U.S. data show little change in the ratio of car travel on highways to total car travel over the historical period considered. It is quite possible, however, especially given the rather rudimentary state of the intercity highway network in much of Canada prior to the 1950s, that use of cars for intercity travel, as a fraction of total car travel, in fact increased over the first three decades of the period covered by our historical estimates. If so, the share of car travel in the estimates in this section is somewhat high for those decades and especially at the beginning of the period.

## 3. INTERNATIONAL COMPARISONS OF MODAL SHARES IN PASSENGER TRANSPORTATION

Chart 2-6 and Table 2-2 in Chapter 2 of Volume 1 present approximate comparisons of the shares of car, bus, train and airplane in total domestic travel by these means for Canada, the United States, Japan, France, West Germany, Italy and the United Kingdom for selected years from 1965 to 1988. The comparative material is used to draw general conclusions as to the prevalence of the dominant role of the car, of the decline in the share of train, and of the rise in the share of air travel in countries whose geography is such that airplanes are attractive as a means of domestic travel.

The footnotes to Table 2-2 warn the reader that the data presented may not be fully comparable across the countries, and thus that small differences in the shares of a mode between two countries may reflect differences in definitions or in data estimation procedures rather than genuine differences in travel patterns. Further, while for purposes of this Royal Commission it would have been preferable to compare shares in domestic intercity travel, reasonably comparable data are only available for total domestic travel, which is the total of urban commuting, other short urban and rural trips, and intercity travel. Thus, the table and chart deal with total domestic travel by these modes. The chief difficulty in measuring domestic intercity travel is to identify the intercity portion of car travel; there is also a grey area in the definition and measurement of urban or rural travel versus intercity travel by bus and train. In Sections 1 and 2 of these Notes to Chapter 2, the rough assumption is made that intercity car travel amounts to two thirds of total car travel on provincial highways. It was judged, however, that there was not sufficient information to make even a rough assumption for the non-North American countries.

This section first sets out the data sources and, where necessary, the assumptions used in developing the estimates. It then briefly discusses the overall results and provides some supplementary information.

## 3.1 THE ESTIMATES

### 3.1.1 Canada

*Car*

The estimates for car (passenger automobiles plus light trucks used for passenger transportation purposes) are based on the estimate for 1990 of total passenger-kilometres of travel by car in Annex 1, Table 2(2)-A1. This estimate is extrapolated backwards using the index of total intercity travel in Table 2(2)-3.

That index was constructed for use as an index of total car travel; it was used earlier as an index of intercity travel by car, given the assumption that the intercity share of total car travel has been constant over time.

*Urban and Intercity Bus*

An estimate of urban bus travel was added to the estimate of passenger-kilometres of intercity bus travel (Table 2(2)-5). Data on vehicle-kilometres of travel by urban buses are available in Statistics Canada's *Urban Transit*, Catalogue No. 53-216, for 1965 and 1970, and *Passenger Bus and Urban Transit Statistics*, Catalogue No. 53-215, for the later years.

For urban buses, an average occupancy rate of 25% was assumed — approximately the same average occupancy rate as is implicit in the U.S. estimates of urban bus passenger-kilometres. Allowing for some increase in the size of an average bus, this implied an average number of passengers per urban bus of 10.5 in 1965, rising to 12 by 1988.

Note that urban rail transit — subways, light rail systems — have been excluded because of difficulties in obtaining data on rail transit systems for some countries. Obviously, for purposes of comparing total travel, it would be preferable to include this means of transportation. The concluding discussion will refer to supplementary data for certain countries.

### *Intercity and Commuter Rail*

This series includes all train travel for intercity and commuter purposes; it thus includes the separate commuter train systems in Toronto and Montreal. The data for 1965 through 1975 are from Statistics Canada, *Historical Statistics of Canada,* 2nd edition, edited by F. H. Leacy, Supply and Services Canada, Ottawa, 1983, series T45, and for the later years are from Statistics Canada, *Rail in Canada,* 1987, Catalogue No. 52-216.

### *Domestic Scheduled Air*

To enhance international comparability, the data on domestic air in Canada and the other countries are taken from a common source — the International Civil Aviation Organization (ICAO). For 1965 and 1970, they are available in the United Nations *Statistical Yearbook,* 1970, and for the later years are available in ICAO, *Civil Aviation Statistics of the World,* using the latest editions in which data for the year in question are shown. The ICAO data for Canada are slightly lower than the series shown in Table 2(2)-5, because the ICAO does not include data on small airlines.

### 3.1.2 United States

*Car*

Estimates of total vehicle-kilometres of travel by passenger automobiles and light trucks in the United States are made by the U.S. Federal Highways Administration (FHWA), and published in U.S. Department of Transportation, FHWA, *Highway Statistics* (for 1988), and *Summary to 1985* (for 1985 and earlier years). Average occupancy rates for passenger automobiles of 2.1 for 1965, 2.0 for 1970, 1.9 for 1975, 1.8 for 1980, 1.7 for 1985, and 1.5 for 1988 have been used. (Estimates from U.S. Nationwide Personal Transportation Study in U.S. Department of Transportation, *National Transportation Statistics,* July 1990.) For light trucks, occupancy of 1.3 was assumed for all years.

*Bus*

Estimates of intercity bus passenger-kilometres are available for all the years of interest (ENO Foundation, *Transportation in America,* 8th edition, 1990). Estimates of urban bus passenger-kilometres are available for 1980 and later years (U.S. Department of Transportation, *National Transportation Statistics, 1988,* for 1988; and American Public Transit Association, *Transit Fact Book,* 1988 edition, for 1980 and 1985). Urban bus passenger-kilometres were extrapolated to earlier years using data on number of passengers (APTA, *Transit Fact Book*).

*Intercity and Commuter Rail*

Estimates of rail passenger-kilometres were taken from the ENO Foundation's *Transportation in America,* 8th edition, 1990.

*Air*

ICAO data, sources as for Canada.

### 3.1.3 Japan

*Car*

Japanese official statistics contain estimates of car travel based on a sample survey of vehicle users. The data for 1965 through 1980 were taken from *Historical Statistics of Japan*, 1987, Vol. 2, Chapter 8, and for later years from the *Japan Statistical Yearbook*, 1991, Chapter 8.

*Bus*

Data on passenger-kilometres are published in the same sources used for car; they are derived from a Ministry of Transport survey of bus operators.

*Rail*

Passenger-kilometres of travel are measured directly and published in the same sources as the car data.

*Air*

ICAO data, sources as for Canada.

### 3.1.4 France, West Germany, Italy and the United Kingdom

*Car*

Data on passenger-kilometres of travel within the country's territory by vehicles registered in the country are published in European Conference of Ministers of Transport, *Statistical Trends in Transport 1965–1988*, Paris, 1992, page 51. The definition of "car" is believed to be similar to that for Canada and the United States, that is, to include passenger automobiles, vans and light trucks used for passenger transportation.

*Bus*

Same source as for cars (page 52). The average occupancy rates for bus differ sharply among the European countries, ranging from 11 in the United Kingdom to 20 in France. Given the lack of good data on bus occupancy and on bus passenger-kilometres, in most countries, it may be appropriate to treat these passenger-kilometre estimates with some caution.

*Rail*

Same source as for cars (page 31). The data refer to all traffic (both residents and non-residents) on the national rail networks of the countries in question. Independent urban railways, and some other small railways, are not included.

*Air*

ICAO data, sources as for Canada.

## 3.2 SUMMARY TABLES AND GENERAL OBSERVATIONS

Estimates of passenger-kilometres for the different means of transportation are shown in Table 2(2)-10. Table 2(2)-11 shows these same data expressed as modal shares for each country (this table is included as Table 2-2 in Volume 1, and was the basis for Chart 2-6). Table 2(2)-12 shows the data in per capita terms. Overall generalizations regarding the dominant role of the car, the declining role of rail, and the increasing role of air have already been noted. Certain further points may be mentioned, some of which also draw on supplementary data available for some of the countries.

*Car*

In terms of per capita travel by car, by air, and in total, Canada occupies an intermediate position between the United States, and western Europe and Japan.

*Table 2(2)-10*

### Domestic Passenger-Kilometres Travelled by Each Mode, Selected Countries, 1965–1988

*(BILLIONS OF PASSENGER-KILOMETRES)*

| Year | 1965 | 1970 | 1975 | 1980 | 1985 | 1988 |
|---|---|---|---|---|---|---|
| **1. Car (autos, light trucks, and vans)** | | | | | | |
| Canada | 198.2 | 253.9 | 300.9 | 337.9 | 310.7 | 341.3 |
| United States | 2,619.1 | 3,208.5 | 3,581.5 | 3,828.8 | 4,229.3 | 4,600.6 |
| Japan | 54.6 | 211.6 | 264.5 | 328.3 | 398.0 | 556.0 |
| France | 198.0 | 304.7 | 374.8 | 452.5 | 494.4 | 554.3 |
| West Germany | 262.5 | 349.6 | 403.3 | 466.5 | 475.8 | 550.5 |
| Italy | 81.2 | 211.9 | 279.3 | 324.0 | 373.7 | 465.4 |
| United Kingdom | 199.0 | 263.0 | 294.0 | 361.0 | 402.7 | 471.3 |
| **2. Urban and intercity bus** | | | | | | |
| Canada | 6.2 | 7.2 | 8.4 | 10.4 | 10.5 | 10.5 |
| United States | 74.2 | 71.8 | 72.3 | 80.1 | 74.1 | 73.2 |
| Japan | 83.9 | 100.8 | 98.7 | 108.8 | 102.0 | 109.0 |
| France | 25.3 | 25.2 | 28.9 | 38.0 | 37.0 | 43.2 |
| West Germany | 39.4 | 48.6 | 58.7 | 65.6 | 54.0 | 52.2 |
| Italy | 28.6 | 32.5 | 42.8 | 58.2 | 66.7 | 77.2 |
| United Kingdom | 59.0 | 53.0 | 55.0 | 45.0 | 42.0 | 41.0 |

**Source: Table 2(2)-10.**

Estimated car travel per capita is substantially higher in the United States than in Canada (18,800 pass-km as compared with 13,200 pass-km, in 1988). However, per capita travel by all means in the United States exceeds per capita travel in Canada by an even larger proportional amount; thus the share of car travel in Canada is slightly higher than in the United States in recent years (90% versus 88%, in 1988). While the error range in the car figures is such that one cannot be certain that the Canadian car share really is slightly larger, it seems likely that this is the case. This is the counterpart of the fact that the U.S. domestic air travel share is clearly very much larger than in Canada.

As noted in Chapter 2, Volume 1, the car share in the western European countries is now approaching the share in North America, but the dominant position of the car is much more recent in western Europe. Japan has the smallest car share, but it is growing rapidly and surpassed rail in the 1980s.

*Bus*

The larger share of bus in Canada than in the United States appears to be due mainly to a larger share of urban bus travel. Intercity bus travel is estimated to account for 0.9% of total domestic travel in

Canada compared with 0.7% in the United States in 1988. (Estimated intercity bus passenger-kilometres per capita are actually slightly higher in the United States (150 pass-km) than in Canada (135 pass-km), although this difference is probably within the error margins of the estimates.) However, using similar bus occupancy assumptions for the two countries, the estimated share of urban bus passenger-kilometres in total travel for Canada is more than twice the share for the United States (1.9% versus 0.7%), and per capita urban bus passenger-kilometres are about 75% higher (270 pass-km versus 150 pass-km). There is reason to believe that Canadian urban bus average occupancy ratio may be substantially higher than U.S. occupancy.[4] If this is the case, the Canadian bus share could be one percentage point or more higher, and of course the contrast with the United States would be even more striking.

Inclusion of estimates of passenger-kilometres for subway and light rail system travel in the urban transit estimates does not change the conclusion that there is much greater use of urban transit in Canada than in the United States. Again, in the absence of official estimates of occupancy rates (or of passenger-kilometres) for Canada, occupancy rates in Canada equal to those implied in U.S. passenger-kilometre data are assumed and applied to Canadian subway and light rail vehicle-kilometre data (Statistics Canada, *Passenger Bus and Urban Transit Statistics*, Catalogue No. 53-215). This yields an estimate of 3.7 billion pass-km of subway/light rail travel for Canada, or roughly half the urban bus passenger-kilometre estimate of 7 billion in 1988. In the United States, subway and light rail passenger-kilometres of 18.9 billion are also equal to roughly half the 36 billion U.S. urban bus passenger-kilometres.

In the United Kingdom, subway and light rail passenger-kilometres are estimated to equal 16% of total bus passenger-kilometres, or 1.2% of total domestic passenger-kilometres (U.K. Department of Transport, *Transport Statistics Great Britain 1979–1989*, London, HMSO, 1990). If this figure is typical of the other western European countries, it suggests that exclusion of subway and light rail urban transit from the tables, while a significant omission in terms of covering the role of urban public transit, does not result in any very significant distortion of the estimated share of the car in total domestic travel.

### *Train*

While train travel has decreased substantially as a share of total travel in all the countries considered, there are also major differences in its role among the countries. Whether considered in terms of share, or in passenger-kilometres per capita, train is clearly much more important in Japan than in the other countries. It is somewhat more important in France than in West Germany, Italy or the United Kingdom. In turn, train travel is several times as important in these west European countries as in Canada and, in 1988, was 50% higher — in passenger-kilometres per capita — in Canada than in the United States. Commuter rail accounts for somewhat more than half of the U.S. rail passenger-kilometres in these estimates (45 pass-km compared with 37 pass-km for intercity rail in 1988). In 1988, commuter rail passenger-kilometres in Canada were 22 per capita, while after the VIA Rail cuts intercity rail in Canada is estimated to be 52 passenger-kilometres per capita.

### *Air*

The differences among countries in air travel's share of total domestic travel appear to reflect, most importantly, differences in geography — with air travel having higher shares in the less compact countries. Including international air travel provides a useful additional perspective on the role of air. Table 2(2)-13 repeats, for 1988, the estimates of domestic scheduled air passenger-kilometres in total and in per capita terms, and the domestic modal shares from Tables 2(2)-10 to 2(2)-12. It also shows ICAO data on international air travel, both scheduled and non-scheduled ("charter"), and the sum of domestic and international air travel. The international air travel passenger-kilometres are added to total domestic passenger-kilometres for all modes to produce an "alternative" measure of total travel. Finally, modal shares are shown using the same passenger-kilometre estimates as in the earlier tables for car, bus and train, the sum of domestic and international travel for air, and expressing the modal figures as percentages of the alternative measure of total travel (including air).

*Table 2(2)-13*

*IMPACT OF INCLUDING INTERNATIONAL AIR TRAVEL WITH DOMESTIC TRAVEL, 1988*

| | Canada | U.S. | Japan | France | Germany | Italy | U.K. |

a. **domestic for all modes plus international air.**

The international air travel data are not for travel by residents of the countries in question, but rather are for international travel provided by carriers that are resident in the country in question. These data only provide a reasonable approximation of international air travel by residents of the country if international air travel services provided to residents by foreign carriers approximately equal international air travel services provided to non-residents by carriers of the country. For most of the countries shown, net exports or imports of passenger air services are believed to be relatively small compared with total international air travel by residents. It may be the case, however, that net exports of air services result in the figure for the United Kingdom giving a somewhat exaggerated impression of international air travel by U.K. residents, and that net imports of air services result in the figure for Italy being an underestimate of international air travel by residents of Italy. Nevertheless, for the countries shown, the estimates of international air travel provided by carriers of the country give an approximate impression of international air travel by residents of the country.

The United States has, by a substantial margin, the highest levels of domestic air travel in terms of passenger-kilometres per capita and in terms of percentage share of total domestic travel. But in per capita terms it has a lower level of international air travel than the United Kingdom or Canada, and a similar level to France and West Germany. The United States has the highest level of total air travel per capita, but Canada and the United Kingdom are not too far behind.

Inclusion of international air travel in total travel of course reduces the shares of all the other modes. Whereas, when only domestic travel was considered (Table 2(2)-11), car travel was estimated to account for a slightly larger share of total travel in Canada than in the United States; car accounts for a somewhat smaller share of total travel in Canada than in the United States if international air travel is included in the total.

## 4. IMPORTANCE OF LONG AND SHORT TRIPS IN DOMESTIC INTERCITY TRAVEL

Chart 2-2 in Chapter 2, Volume 1, shows the number of trips in Canada in 1990 by categories of one-way distance from 80–159 kilometres to over 1,600 kilometres, as reported in the Canadian Travel Survey (CTS). Chapter 2 mentions that, in 1990, 76% of intercity trips taken were between 80 and 320 kilometres in one-way distance, but also notes that trips over 320 kilometres in one-way distance accounted for more than 60% of intercity passenger-kilometres travelled.

This brief note provides estimates that compare the shares in number of trips, and in passenger-kilometres, for trips in the different length categories (Table 2(2)-14). Both the shares of trips, and the shares of passenger-kilometres, are based on Canadian Travel Survey data for 1990. Calculation of the shares of passenger-kilometres requires use of unpublished data from the survey on average trip length in the different length categories. Estimates of both types of share are of course subject to the limitations of the CTS data discussed in Section 1 of these notes; in particular it is quite possible that recall problems by respondents result in some relative underestimation of shorter trips.

The total number of trips, and total passenger-kilometres of travel, are consistent with the numbers reported in the "CTS-based" estimates in Table 2(2)-1, allowing for the fact that Table 2(2)-1 counts one-way trips while Table 2(2)-14 (and Chart 2-2) count round trips, and for the fact that Table 2(2)-1 excludes trips by means other than car, air, bus, rail and ferries.

Longer trips of course account for a much larger share of total passenger-kilometres than of numbers of trips. In particular, trips over 800 kilometres in one-way distance account for 39.2% of passenger-kilometres but only 6.3% of total trips, and trips over 1,600 kilometres in one-way distance account for 26.5% of passenger-kilometres of intercity travel but only 2.6% of the number of trips.

*Table 2(2)-14*

### DOMESTIC INTERCITY TRAVEL BY LENGTH OF TRIP, 1990

*(SHARES IN NUMBER OF PERSON-TRIPS AND IN PASSENGER-KILOMETRES OF TRAVEL)*

| | Person-trips | | Average round-trip distance (km) | Passenger-kilometres | |
|---|---|---|---|---|---|
| | ('000s) | (%) | | (millions) | (%) |
| **Trips — one-way distance** | | | | | |
| 80–159 km | 62,278 | 46.5 | 219 | 13,650 | 16.8 |
| 160–319 km | 39,587 | 29.6 | 427 | 16,897 | 20.8 |
| 320–799 km | 20,420 | 15.3 | 930 | 18,984 | 23.3 |
| 800–1,599 km | 4,954 | 3.7 | 2,079 | 10,297 | 12.7 |
| 1,600–3,199 km | 2,192 | 1.6 | 4,299 | 9,424 | 11.6 |
| 3,200 km or more | 1,401 | 1.0 | 8,656 | 12,127 | 14.9 |
| Not stated | 2,999 | 2.2 | | | |
| Total | 133,831 | 100.0 | 608 | 81,375 | 100.0 |

**Note:** Component percentage shares may not sum exactly to 100% due to rounding.

# ENDNOTES

1. The occupancy rate is based on information from D. Ward's *Profile of the Intercity Bus Industry* (Transport Canada, May 1990), p. 5, and material provided to the Royal Commission by several large intercity bus firms. Ward judges typical occupancies to be about 18 passengers per bus in Canada, but, based on the occupancies recorded by the large firms, we judge that a somewhat higher assumption is appropriate. In our estimate, the system average number of passengers has been assumed to be 21, which is an occupancy rate of 50% or an average of 42 seats per bus.

2. Derived from Dennis Ward, "The Cruise Industry," Transport Canada, TP9163, April 1988. The estimate in this source of 157,000 passengers for 1987 is extrapolated forward at a 4% annual growth rate, and an allowance of 20,000 for inland waters cruise passengers is added.

# ANNEX 1

## CAR TRAVEL — TOTAL AND HIGHWAY

No direct data on total vehicle-kilometres or passenger-kilometres of travel by car exist, but approximate estimates of vehicle-kilometres may be derived in two ways:

- using statistics on sales of gasoline for road use coupled with estimates of average fuel consumption per kilometre; or
- using statistics on the total stock of passenger motor vehicles coupled with estimates of average annual distance travelled per vehicle.

Using both approaches, this Annex first develops estimates of vehicle-kilometres of travel for both "passenger automobiles" and for "light trucks" (four-wheel vehicles, other than passenger automobiles, under 4,500 kg in laden weight, such as, pickups, minivans and 4-wheel drive vehicles) used for passenger transport. Separate data on the amount of travel on provincial highways by these classes of vehicle are then considered. Finally, assumptions as to the number of occupants per vehicle are introduced in order to arrive at rough estimates of the number of passenger-kilometres of travel by car in total and on highways.

### A1.1 TOTAL TRAVEL — VEHICLE-KILOMETRES

**Gasoline Sales Plus Fuel Economy**

Sales of gasoline taxed for use in road motor vehicles totalled 31.8 billion litres in 1990 (Statistics Canada, *Road Motor Vehicles — Fuel Sales, 1990*, Catalogue No. 53-218). Unpublished National Energy Board studies for the mid-1980s suggest that 65% of sales are for passenger automobiles, with the remainder being consumed in other vehicles, such as light trucks, non-diesel heavier trucks and buses, and motorcycles. Fragmentary evidence suggests that about 80% of this remaining 35% of sales, or 8.9 billion litres, is for light trucks.

Statistics Canada's *Fuel Consumption Survey*, Catalogue No. 53-226, which was last conducted for 1988, provides what are believed to be quite reliable estimates of average fuel economy for passenger automobiles and light trucks for the period covered by the survey. These estimates are 12.0 litres per 100 kilometres for passenger automobiles in 1988, and 16.6 litres per 100 km for light trucks in 1987. While there may have been some improvement in average fuel economy since 1988, these estimates are used. Applied to the gasoline sales estimates, they suggest total travel in 1990 of 172.5 billion vehicle-kilometres for passenger automobiles, and 55 billion vehicle-kilometres for light trucks.

### Stock of Cars Plus Average Annual Use

Personal-use passenger automobiles sampled by the Fuel Consumption Survey were driven an average of 17,400 kilometres in 1988, while light trucks were driven an average of 18,200 kilometres. The stock of vehicles to which these average distances should be applied is less than the figures appearing in Statistics Canada's *Road Motor Vehicles — Registrations* (Catalogue No. 53-219). During sampling for the fuel consumption surveys it was found, for 1983, that about 8% of registered passenger automobiles had been scrapped, 2% of registrations were duplications, and another 10% were in existence and operable but out of service in dealers' hands, in storage or under repair.[1] Passenger automobile registrations for 1990 were 12.6 million. Applying the estimate of average annual kilometres driven (17,400 for passenger automobiles) to 80% of the registrations level (or 10.1 million vehicles) suggests 175.6 billion vehicle-kilometres of travel by passenger automobiles in 1990, compared with the estimate of 172.5 billion vehicle-kilometres derived using gasoline sales. A rounded estimate of 175 billion vehicle-kilometres of travel for 1990 is used.

Motor vehicle registration figures are believed to include most light trucks, as defined earlier, in the "trucks" sub-category of "commercial vehicles." There were 3.9 million "trucks" registered in 1990, of which 500,000 are estimated to be heavy trucks,[2] suggesting 3,400,000 light trucks. Assuming that, as for passenger automobiles, the number of light trucks in use is only about 80% of the number of light truck registrations, suggests that the 18,200 average annual kilometres of use figures should be applied to about 2,700,000 light trucks in use, yielding an estimate of 49 billion vehicle-kilometres. This compares with the estimate of 55 billion vehicle-kilometres derived using fuel sales data. A rounded estimate of 50 billion vehicle-kilometres for 1990 is used. Further, it is assumed that 80% of this amount, or 40 billion vehicle-kilometres, were for private passenger transport, with the remainder for freight use.

---

[1] E. Lawrence, *Fuel Consumption Data Book*, Technical Memorandum TMSE 9102, Transport Canada, March 1991, pp. 111-15.

## A1.2 HIGHWAY TRAVEL — VEHICLE-KILOMETRES

The estimates are based on the study for the Royal Commission by Nix, Boucher and Hutchinson in Volume 4 of this Report, which uses provincial highway traffic count data. With the modification discussed in Notes to Chapter 3, subsection 5.1.1 of this Volume, it is estimated that travel on provincial highways by passenger automobiles was about 97.5 billion vehicle-kilometres in 1990 and 100 billion vehicle-kilometres in 1991. Travel by light trucks in use for passenger transportation purposes is estimated to be 19 billion vehicle-kilometres in 1990 and 20 billion in 1991.

## A1.3 PASSENGER-KILOMETRES OF TRAVEL

There is very little information on the average number of occupants per passenger automobile or light truck overall or in different types of use. Estimates for the United States from the Nationwide Personal Transportation Survey (NPTS) indicate an overall occupancy rate of 1.5 for 1990, with average occupancy ranging from 1.1 for work trips, through 1.5 for shopping trips, 1.7 for other family/personal trips, to 1.8 for social/recreational trips. Canadian vehicle ownership per capita or per household is somewhat lower than in the United States, and it is reasonable to assume that average occupancy is somewhat higher. Average occupancies for passenger automobiles of 1.8 persons in highway driving, and 1.5 persons in other (primarily urban) driving, are assumed. For light trucks, given the predominance of pickup trucks with fewer seats than cars, average highway occupancy of 1.5 persons and average other occupancy of 1.2 are assumed.

---

[2] See Appendix A of Fred P. Nix, Michel Boucher and Bruce Hutchinson, "Road Costs," in Volume 4 of this Report.

These occupancy assumptions, when combined with the vehicle-kilometre estimates, yield the estimates of passenger-kilometres of highway and total travel in 1990 shown in Table 2(2)-A1.

*Table 2(2)-A1*

*ESTIMATES OF VEHICLE- AND PASSENGER-KILOMETRES: CAR, 1990*

| | Veh-km (billion) | Pass-km (billion) |
|---|---|---|
| **Passenger automobile** | | |
| Highway | 97.5 | 176 |
| Other | 77.5 | 116 |
| Total | 175 | 292 |
| **Light truck in passenger transportation use** | | |
| Highway | 19 | 29 |
| Other | 21 | 25 |
| Total | 40 | 54 |
| **Both ("car")** | | |
| Highway | 116.5 | 205 |
| Other | 98.5 | 141 |
| Total | 215 | 346 |

These estimates are used as the basis for a number of other estimates in Sections 1, 2 and 3 of the Notes to Chapter 2. In Section 1, two thirds of the highway total of 205 billion passenger-kilometres, or a rounded 135 billion passenger-kilometres, is used as a rough estimate of intercity car travel. In Chapter 3 of Volume 1, 210 billion passenger-kilometres is shown as the estimate of total passenger-kilometres of car highway travel for 1991. In Section 3, the 346 billion estimate of total car travel for 1990 (rounded to 350 billion) is used in calculating the 1988 Canadian figure for the international comparison of total travel by the different means of transportation.

## INTRODUCTION

Chapter 3 presents estimates of Canadian (average and total) domestic intercity passenger modal costs and average modal costs for four illustrative routes. Chapter 18 includes projections of system total and illustrative route-specific average costs to the year 2000.

These modal estimates encompass:

- infrastructure;
- environmental costs;
- accident costs;
- transportation taxes and fees; and
- vehicle and carrier operations.

The cost estimates are split into the portion of the cost paid by the users or travellers and the portion of average cost paid by the taxpayer, by other travellers on other routes and by society in other than financial terms, for example, through suffering the effects of pollution.

## 1. UNDERSTANDING THE TABLES

The tables in Volume 1, Chapters 3 and 18 are intended to portray the costs of domestic passenger transportation in Canada including environmental and accident "costs," currently borne by the public, and the cost and financial implications, to users and taxpayers, of the Royal Commission's recommendations. Table 3(2)-1 reproduces the illustrative system-average costs from Table 3-1 of Volume 1.

To help the reader understand what the estimates in Table 3(2)-1 cover, Table 3(2)-2 provides a hypothetical expansion of the portion of a table showing results for a particular means of travel. This table could illustrate average costs per passenger-kilometre, total costs in millions of dollars, or current and projected costs per trip on a specific route. It could apply to the 1991 cost estimates of Volume 1, Chapter 3 or it could apply to the scenario projections of Volume 1, Chapter 18. The numbers used have no significance; they are intended purely to help explain the meaning of the table components.

*Table 3(2)-1*

### Illustrative System-Wide Average Annual Costs of Intercity Domestic Travel (Cents per passenger-kilometre)

| | Car | | | Bus | | |
|---|---|---|---|---|---|---|
| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 0.0 | 2.1 | 2.1 | 0.0 | 0.3 | 0.3 |
| **Environmental** | 0.0 | 0.6 | 0.6 | 0.0 | 0.2 | 0.2 |
| **Accident** | 3.7 | 0.1 | 3.8 | 0.4 | 0.0 | 0.4 |
| **Special trans. tax/fee** | 1.2 | −1.2 | 0.0 | 0.3 | −0.3 | 0.0 |
| **Vehicle/Carrier** | 10.9 | 0.0 | 10.9 | 8.4 | 0.2 | 8.6 |
| **Total** | **15.8** | **1.6** | **17.4** | **9.1** | **0.4** | **9.5** |

| | Airplane | | | Train | | |

| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 2.2 | 3.4 | 5.6 | 2.9 | 0.0 | 2.9 |
| **Environmental** | 0.0 | 1.0 | 1.0 | 0.0 | 0.6 | 0.6 |
| **Accident** | 0.1 | 0.0 | 0.1 | 0.2 | 0.0 | 0.2 |
| **Special trans. tax/fee** | 0.6 | −0.6 | 0.0 | 0.4 | −0.4 | 0.0 |
| **Vehicle/Carrier** | 14.4 | 0.0 | 14.4 | 7.4 | 32.8 | 40.2 |
| **Total** | **17.3** | **3.8** | **21.1** | **10.9** | **33.0** | **43.9** |

| | Ferry | | | All intercity travel | | |
|---|---|---|---|---|---|---|
| **Type of cost** | **Users** | **Others** | **Total** | **Users** | **Others** | **Total** |
| **Infrastructure** | 0.0 | 4.7 | 4.7 | 0.2 | 2.2 | 2.4 |
| **Environmental** | 0.0 | 2.0 | 2.0 | 0.0 | 0.6 | 0.6 |
| **Accident** | 0.1 | 0.0 | 0.1 | 3.3 | 0.1 | 3.4 |
| **Special trans. tax/fee** | 0.9 | −0.9 | 0.0 | 1.1 | −1.1 | 0.0 |
| **Vehicle/Carrier** | 24.1 | 11.6 | 35.7 | 11.2 | 0.2 | 11.4 |
| **Total** | **25.1** | **17.4** | **42.5** | **15.8** | **2.0** | **17.8** |

**Note:** **In order to illustrate smaller components, averages are shown to the nearest tenth of a cent. In general, cost estimates are approximate and are not accurate to this level of precision. See text.**

*Table 3(2)-2*

COST TABLES ILLUSTRATION: HYPOTHETICAL EXAMPLE
(DOLLARS)

| | Costs borne by: | | | | | Total costs |
|---|---|---|---|---|---|---|
| | | Others | | | | |
| | | | Government | | | |
| **Type of Cost** | **Users** | **Travellers** | **Federal** | **Provincial** | **Public** | |
| **Infrastructure** | | | | | | |
| Links | 25 | | –6 | | | 19 |
| Terminals | 15 | | 3 | | | 18 |
| Control | | | 2 | | | 2 |
| **Environmental** | | | | | 24 | 24 |
| **Accident** | 4 | | | 1 | | 5 |
| **Special trans. tax/fee** | | | | | | |
| Fuel taxes | 16 | | –9 | –7 | | 0 |
| Licence fees | 1 | | –1 | | | 0 |
| **Vehicle/Carrier** | 333 | –35 | | 3 | | 301 |
| **Total** | **394** | **–35** | **–11** | **–3** | **24** | **369** |

The key element of the sample expansion is the column "others," which identifies four categories of cost sustainers and funds providers or recipients: travellers, federal government, provincial government and the public. Also, the infrastructure row is subdivided in this example into links, terminals and control; and the special transportation tax/fee row, into fuel taxes and licence fees. Of course, other categories might apply.

Starting with infrastructure, in terms of airplane travel, the $25 shown for links in the users column could indicate a traveller payment of Air Transportation Tax. This exceeds, by $6, the $19 total cost of air navigation support paid by the federal government as shown in the total column. Thus, the $6 is shown as negative, being a net revenue gain to the federal government. For terminals, $15 in landing fees represents an under-recovery of airport costs by $3. In the column others/government/federal, the traffic control cost of $2 is shown as not recovered, by a specifically designated payment.

In the environmental row, a cost to the public of $24 is shown. This represents a valuation estimate of the physical effects of environmental damage experienced by members of the public. At present, no transactions related to these costs occur.

The treatment of accident costs is more interesting analytically. The traveller, through her or his fare via the carrier's insurance cost, is shown as paying $4 and the provincial government pays $1, in medicare. Were this means of travel a road vehicle, the accident cost imposed on the occupants of other vehicles and not fully compensated by the travellers and their insurance would be included under users. This is based on the view that incurring the risk of such costs is part of the "price" paid when one travels by road. An alternative approach would be to separate out accident costs to other travellers and include them as a further "others" sub-category.

Special transportation taxes and fees, from the point of view of others, are government revenues, and are represented by negative costs of $9 in fuel taxes and $1 in licence fees paid by the traveller to the federal government (actually paid by the carrier from the traveller's fare). The $7 under provincial fuel taxes, a negative cost to provincial governments, represents the traveller's share of this tax; this is an estimate of the amount that exceeds the provincial sales tax that applies generally.

The vehicle/carrier cost of $333 under users may be viewed as the balance (on average) of what a traveller pays toward his or her total fare that is attributable to cost items other than those represented in the rows above it in the matrix.

Viewing the other elements of the vehicle/carrier row, travellers are shown as receiving a $35 "cross subsidy,"[1] and the provincial government is shown as paying a subsidy of $3, presumably direct, toward vehicle/carrier costs.

The total row indicates that travellers pay an average fare of $394. Because the average total cost of the hypothetical trip is $369, the average traveller appears to pay $25 more than the costs concerned — if one does not subtract the $35 cross subsidy to other travellers. Although the federal and provincial governments have net financial gains of $11 and $3 respectively, this does not balance a $24 cost to the public for environmental damage.

As mentioned, Table 3(2)-1 and the tables of Chapters 3 and 18 use a more condensed format in which the "others" columns, the "infrastructure" and "special transportation tax/fee" rows are not subdivided. The expanded, illustrative table shows the possible components of a single entry in the condensed format.

## 2. COSTING BASIS

Among the modes, the consistency of costing basis was limited by the structure of the data available for each mode. With the exception of the car, and with it vans and light trucks, costing and cost estimates were confined to public unit toll travel. Private airplane and boat transportation were not included. Chartered aircraft (true charters where the aircraft is leased generally with crew, fuel and supplies — not low priced travel, with tickets, that may be advertised as charter), bus and boat travel were also excluded where the data allowed.

In the case of bus, this was an important exclusion. It is estimated that 2.6 billion bus passenger-kilometres[2] were on domestic-origin, non-urban, non-school chartered service. This compares with the estimated 3.3 billion passenger-kilometres for scheduled domestic intercity bus services, which are the subject of the cost and other bus references of Volume 1.

Where possible, the costs presented are for domestic origin and destination travel. In some cases the domestic portion of international trips have been included; for the automobile, rail and bus, all travel within Canada was included. For air, international flights that originate or terminate in Canada and overflights of Canadian airspace were excluded; however, it was not possible to exclude domestic flights (separate ticket coupon) that were part of what was essentially an international trip.

## 3. COSTING PRINCIPLES

In general, the analysis is intended to produce an estimate of long-run average costs for the industry. Thus, all costs, including those of head office, were attributed to services they presumably support. Unless there was evidence that joint costs were attributable to less than the total product mix, these costs (for example, for VIA Rail stations) were allocated or attributed to services primarily on the basis of volume of use.

The ways in which density, speed, stage or journey length affected costs were considered and incorporated in developing cost estimates for types of routes.

An opportunity-cost-of-capital rate of 10% real (10% plus inflation) was used for all operators and modes. This figure is recommended for use throughout the federal government[3] as a social discount rate, and, when adjusted for inflation, is very close to the cost-of-capital rate for CP as calculated by the National Transportation Agency.

Wherever practical, capital costs of equipment and infrastructure (depreciation and cost of capital) were treated on a current value basis.[4] For most equipment and infrastructure this amounted to replacement value costing. Essentially, depreciation and the 10% real cost of capital, applied to the replacement cost of the remaining capital investment, were taken as representative of the full opportunity cost of invested capital. Also included as a capital charge was the opportunity cost of capital invested in the land occupied by road, track, airport and port infrastructure wherever the magnitude of this cost was believed to be substantial — primarily airport property.

Applying a common rate of capital cost to estimates of the replacement value of the capital stock in use helps make cost estimates for the different modes comparable. In particular, these cost estimates are not affected by differences in the extent to which a given entity is debt financed or may have received what might be viewed as equity capital at no charge from governments.

## 4. DATA AND COST DEVELOPMENT

The system average or typical cost estimates that follow were developed from the data available, with gaps filled on the basis of engineering costing, essentially aggregating the costs of the inputs, and on quoted ticket prices.

Statistics Canada publications were the primary sources of data for the system-wide costs. For costing purposes, Statistics Canada provided special aggregations of data. Data were also obtained from provincial authorities; Transport Canada; the Transportation Association of Canada; Canadian air, bus, ferry and railway carriers; and published studies. The key source of data for the carrier costs on the illustrative routes provided in Volume 1 was the industry. The response of the airline, railway, ferry and bus companies to requests for detailed cost, revenue, traffic and market data was most gratifying. In some cases, however, data were provided on a confidential basis. Respecting this confidentiality limits the specificity or extent of detail that can be reported for some of the cost estimates.

Most of the costs were estimated for 1989 or the organizations' fiscal year 1989–90, but some 1990 and 1991 data were used, and in some cases it was necessary to use pre-1989 data. The estimates were adjusted approximately to 1991 cost and price levels.

Costs were intended to represent normal 1991 conditions, but many of the input data were, as has been noted, from other recent years. Where there were reasonable grounds to suggest changes that had occurred to 1991, such changes were incorporated, and all estimates were converted to 1991 prices.

The illustrative 1991 costs used are not an estimate of actual 1991 levels; 1991 was an unusual year with some major carriers suffering large losses. The 1991 year carried surprises and anomalies that are not expected to persist. An attempt was made to represent the longer-term trend. All costs are in 1991 prices, but essentially represent a "normal" recent year.

The system-average costs by mode in Chapter 3 were estimated in cents per passenger-kilometre (¢/pass-km). The estimates of total costs by mode for 1991 were obtained by multiplying these system-average costs by the Royal Commission's estimates of total passenger-kilometres in that year.

# 5. INFRASTRUCTURE COSTS

## 5.1 CAR

### 5.1.1 Costs of Highway Construction and Maintenance

Estimates are based on the report to the Royal Commission by Nix, Boucher and Hutchinson,[5] in Volume 4 of this report. The study estimates the total costs for deterioration and maintenance of the provincial paved highway system, based on estimates published by the Transportation Association of Canada as well as Canadian models of highway-lifecycle costs. The study's estimates, by necessity, are very approximate. This is due primarily to uncertainty in the causes and attribution of road wear, but also in part to uncertainty in the spending estimates. The absence in Canada of data on highway traffic by vehicle weights and axle configurations particularly contributes to these uncertainties.

An important unresolved technical question is the extent of interaction between pavement deterioration due to climate and deterioration due to wear. The report effectively assumes there is no such interaction, as do these notes.

It is possible that deterioration identified by Nix et al. as being separately caused by climatic conditions is in fact the joint result of climate and traffic, and that the traffic contribution is therefore underestimated. Research to date has not adequately explored this relationship, and it remains an important issue for research into the design of a correct cost attribution and pricing regime.

The tentative allocation of costs to vehicle classes in the Nix et al. report provides the basis for the estimates of infrastructure costs in Table 3(2)-1, but with two important modifications:

- Nix et al. allocated all common costs (including those parts of pavement deterioration dependent on climate rather than wear, common annual maintenance items, and administrative costs) according to vehicle-kilometres by vehicle class. Royal Commission staff calculations have instead allocated these costs according to vehicle-kilometres weighted by "passenger-car-equivalent" units (PCEs), with an average heavy truck representing 2.5 PCEs, and an average bus, 2 PCEs.
- The report estimated total traffic wear on the provincial highway systems as 158 billion vehicle-kilometres, about 43 billion of which was on the "middle 30%" of paved two-lane rural highways. This seems high based on the evidence presented (from counting vehicles using each class of highway in some provinces), and an annual average daily traffic (AADT) of 2,000 vehicles instead of 3,000 has been assumed for these highways, thereby reducing the estimate for this sub-network to about 28 billion vehicle-kilometres and the total for the provincial network to 144 billion vehicle-kilometres.

The resulting estimated costs by class of road are shown in Table 3(2)-3. While costs per route-kilometre to build highways to higher standards are greater, such highways tend to have high traffic volumes over which those costs are spread. Therefore, costs per passenger-kilometre are lower on the higher quality and higher traffic density highways.

*Table 3(2)-3*
*ESTIMATED CONSTRUCTION AND MAINTENANCE COSTS BY CLASS OF HIGHWAY*
*(1989 CENTS PER VEHICLE-KILOMETRE)*

| Road class | Annual average daily traffic (number of vehicles) | Costs by vehicle type | | |
|---|---|---|---|---|
| | | Car/ light truck | Heavy truck | Bus |
| Expressway | 12,000 | 0.47 | 2.62 | 1.06 |
| Other paved highways: | | | | |
| Densest 10% | 6,000 | 0.71 | 3.99 | 1.56 |
| Medium 30% | 2,000 | 1.77 | 9.79 | 3.71 |
| Least dense 60% | 700 | 4.77 | 21.38 | 9.77 |
| Average highway | — | 1.46 | 5.48 | 3.00 |
| Cents per pass-km | — | 0.83 | — | 0.14 |
| Cents per pass-km, in 1991 prices | — | 0.91 | — | 0.15 |

The costs as estimated are identical for cars and light trucks. The final two rows (in ¢/pass-km) for car and light truck costs represent averages combined in proportion to their passenger-kilometres, using the standard assumptions of average occupancies of 1.8 passengers per car and 1.5 passengers per light truck, giving a combined average of 1.76. The estimates of costs per passenger-kilometre for buses assume average occupancy of 45% of 47 seats, or 21.15 passengers per bus.

### 5.1.2 Cost of Highway Capital

While depreciation (pavement deterioration) is included in the estimates, the cost of capital for highway infrastructure must be added. The Royal Commission staff estimates of highway cost of capital are quite speculative. Very little information is available to allow estimation of the size of the highway capital stock. A study by Lall, in Volume 4 of this report,[6] updating earlier work for the Canadian Transport Commission and Transport Canada,[7] suggests the entire road network stock amounted to about $52 billion in 1988. Updated only by inflation, this would have amounted to about $59 billion in 1991. The proportion of this that is for intercity or extra-urban highways can only be guessed.

The paved provincial highway network to which the estimates of Nix et al. apply, consists of about 140,000 two-lane kilometres, of a total of 880,000, or 16%. This relatively small proportion, however, includes all of the costly provincial expressways[8] and highways through urban areas, and all paved rural highways, which are of higher quality and cost than unpaved provincial or municipal roads or than municipal streets. For illustrative purposes, it is guessed that the paved highways are 40% to 60% of the total capital stock; that is, $24 billion to $35 billion.

The amount of these costs that is attributable to car and light truck traffic must be estimated next. The allocation by PCEs attributes 59% of common highway costs to passenger cars, and 15% to light trucks. It is assumed that about 80% of light truck use is for passenger travel, so the total proportion of highway cost for cars and light trucks in passenger use is estimated at 70%. Applying the same proportion to the capital costs, the costs attributed to cars and light trucks would amount to $16 billion to $25 billion.

Then this cost must be converted to an annual amount. The assumption throughout these cost estimates has been that the appropriate (opportunity-cost) rate with which to calculate the annual cost attributable to capital investment is 10% per year. The highway cost of capital attributed to passenger cars would therefore amount to $1.6 billion to $2.4 billion.

Finally, the cost per passenger-kilometre can be estimated by averaging the annual capital cost over total travel of 210 billion passenger-kilometres. These very rough computations suggest the value is in the range of 0.8¢/pass-km to 1.12¢ pass-km. As this is of the same order of magnitude as the earlier estimate of the highway deterioration/maintenance cost per passenger-kilometre, and relies on such rough reasoning, the capital charge is incorporated by simply doubling the deterioration/maintenance cost for each class of vehicle and type of highway.[9]

In consequence, the cost for cars of road infrastructure is estimated as 0.91 × 2 = 1.82¢/pass-km.

### 5.1.3 Land Costs

A difficulty in allowing for land costs is that if they are included in the accounts of transport authorities at all, they are likely to be based on historical purchase prices, which do not adequately represent current values. More particularly, they do not represent the value the land would have if liberated for other use. This is essentially an argument that the appropriate value to include is the "opportunity cost," that is, the value of the land in alternative use.

An attempt to estimate the opportunity cost of highway land is described in Annex 1 to these Notes. Using simple assumptions, it is estimated that the 137,236 route-kilometres of provincial highways in Canada in 1990 used some 475,000 hectares of land (or 1.17 million acres, about 1,800 square miles). If valued entirely as farmland, this had a value of some $580 million. If the alternative use included residential development of about 1% of the land, at an average value of $370,000 per hectare, the cost amounted in 1990 to $2.4 billion.

Converting this latter amount to an annual rate, using 10% per year as the opportunity-cost rate for capital assets, as indicated earlier, then allocating land cost among vehicle types according to PCE-km, and finally averaging the car cost over 210 billion passenger-kilometres, the resulting estimate is 0.08¢/pass-km. Given the uncertainty in this estimate, particularly in forecasting alternative use of the land, it is incorporated in the highway infrastructure costs as a rounded 0.1¢/pass-km.

### 5.1.4 Costs of "Control"

In addition, an amount is added for the "control" costs of infrastructure, consisting of the police enforcement costs and driver/vehicle enforcement and control programs for cars, analogous to the air traffic control and navigation systems in other modes. Some sparse evidence suggests police traffic-control costs amounted in 1987 to about $450 million per year.[10] Vehicle and driver registration fees amount to about $64 per vehicle per year,[11] or about $850 million per year. It is guessed for illustrative purposes that these fees just balance the provincial expenses on police traffic services and the other relevant program costs — that is, that the control component of infrastructure costs amounts to about $64 per year in 1990 prices, or 0.36 cents per vehicle-kilometre (¢/veh-km) over an average 17,600 kilometres per vehicle per year. Converted to 1991 prices, and averaged over 1.76 passengers per vehicle, this amounts to 0.22¢/pass-km.

Total infrastructure costs for cars, including construction and maintenance, land and control are finally estimated as 1.82 + 0.1 + 0.22 = 2.14¢/pass-km.

### 5.1.5 Car "User-Borne" Infrastructure Costs, from Road Tolls

The only significant road tolls in Canada are those for the Coquihalla Highway in British Columbia.[12] Revenues were $18.4 million in fiscal year 1988–89, $21.2 million in 1989–90,[13] and $32.9 million in 1990–91.[14]

Separate estimates of revenues from passenger cars and trucks are not available, but a rough guess is sufficient for present purposes. It can be guessed that the total from cars and privately used light trucks would have been about $20 million in 1991.

Because national highway traffic in 1991 is estimated at 210 billion passenger-kilometres, these Coquihalla tolls would have amounted to about 0.01¢/pass-km, clearly not sufficiently large to appear in the system-average car infrastructure costs per passenger-kilometre of Table 3(2)-1.

## 5.2 BUS

### 5.2.1 Highway Construction and Maintenance Costs

The highway infrastructure costs for buses are shown in Table 3(2)-3. They were obtained from the estimates of Nix et al. and modified to allocate all common components by PCE-km with an intercity bus comprising two PCEs. The traffic estimates for bus by type of highway are even more approximate than those for cars and heavy trucks.

The costs per vehicle-kilometre in Table 3(2)-3 are divided by an average occupancy of intercity buses of about 21 passengers, obtained from an average load factor of 45% for an average 47-seat bus, from the investigation of bus carrier costs by Royal Commission staff and consultants.

The weighted average cost for all road types amounts to 0.146¢/pass-km in 1991 prices (rounded in Table 3(2)-3 to 0.15¢/pass-km).

Capital charges are added to this cost following the same reasoning as for car infrastructure costs: that it seems legitimate as a first approximation to **double** the estimated road deterioration costs to allow for charges on the remaining capital value of the road structures. The total costs therefore become 0.146 × 2 = 0.292¢/pass-km.

### 5.2.2 Land Costs

Opportunity costs of highway land attributable to buses can be estimated as for cars, allocating the total opportunity costs, estimated at $240 million per year, according to PCE-km. Intercity buses contribute only some 0.2% of total PCE-km. Their share of land costs would then be about $0.5 million per year. Averaged over total bus travel of 3.3 billion passenger-kilometres, this would amount to 0.02¢/pass-km.

Total bus infrastructure "way" costs, including land, are thus rounded to 0.3¢/pass-km. Costs of traffic control for buses are assumed to be too unimportant to change this rounded total.

## 5.3 COMPARISON OF COSTS AND REVENUES FOR HEAVY TRUCKS

The procedures to identify highway infrastructure costs for cars/light trucks and buses also produce estimates for "heavy trucks" (the class heavy truck refers to any truck with a gross vehicle weight rating over 4.5 tonnes, though the maximum permitted nationally is 62.5 tonnes).[15] The report for the Royal Commission on road construction and maintenance costs provided its interpretations of the relationships between costs and truck axle configurations, axle weights and gross vehicle weights.[16] It allocated common components of costs arising from deterioration due to climate together with central costs of administration on the basis of vehicle-kilometres driven. Its methods provide an estimate of 1989 costs for the provincial highway systems for an average heavy truck of 3.82¢/veh-km, or about 4.17¢/veh-km in 1991 prices.[17]

The Royal Commission staff modifications to those estimates included allocating all common components of costs by PCE-kilometres, with an average heavy truck being 2.5 PCEs. The allocation procedure can then be reduced to the following formula, based on gross vehicle weight (GVW) and equivalent-standard-axle loads (ESALs)[18] as well as PCEs:

**Cost per vehicle-kilometre in 1989 ¢**
**= 0.0235(GVW) + 1.5602(ESALs) + 1.037(PCEs)**

The average heavy truck above consists of 23.3 tonnes GVW, with 1.5 ESALs, and 2.5 PCEs. Its costs then become 5.48¢/veh-km, or approximately 6¢/veh-km in 1991 prices. To allocate fully all highway costs, as was done earlier for passenger cars/light trucks, a cost of the invested capital should also be included. A preliminary approximation, in the absence of a confident estimate of the stock of highway capital, suggests this would be of a broadly similar order to the construction and maintenance cost, about 4¢ to 6¢/veh-km in 1991 prices.[19] The total cost for the average truck then becomes 10¢ to 12¢/veh-km.

Average truck revenues have been estimated using schedules of registration fees for trucks obtained from the provincial governments of Nova Scotia, New Brunswick, Ontario and Saskatchewan, together with a function relating truck fuel consumption to gross weight obtained from a study of road user costs and revenues for Transport Canada.[20] The fuel tax rate is the Canadian average estimated for diesel fuel in 1991 of 13.1¢ (net of normal sales taxes).

For the average heavy truck, the registration fee is approximately $1,000 per year and the fuel tax rate approximately 6¢/veh-km. The revenue from such a truck would be less than the fully-allocated costs of 10¢ to 12¢/veh-km for a truck travelling more than about 20,000 kilometres per year; and for such a truck travelling 100,000 kilometres per year, the excess of cost over revenue would be $3,000 to $5,000.

Similar computations can be made for some typical truck configurations suggested in the report to the Royal Commission by Nix et al., as follows:

| Configuration | Gross weight (tonnes) | Average cost (¢/veh-km) | Registration fee per year ($) | Average fuel tax (¢/veh-km) |
|---|---|---|---|---|
| Straight truck (T3) | 25 | 11–14 | 1,000 | 6.1 |
| Tractor-semitrailer (3-S2) | 39 | 15–19 | 1,700 | 7.1 |
| B-double (3-S3-S2) | 62 | 20–26 | 3,000 | 9.6 |

Revenues would be substantially outweighed by costs for each of these types of trucks if they are used for more than about 20,000 kilometres per year. Using the upper bounds of the cost estimates, the cost for the 25-tonne straight truck used for 50,000 kilometres per year would outweigh revenues by about $3,200; while if the tractor-trailer and tractor-double-trailer trucks were used for 100,000 kilometres per year their costs would outweigh revenues by approximately $10,000 and $13,000 respectively.[21]

Marginal costs would, of course, be lower than the above fully allocated average costs. The research report to the Royal Commission included an initial exploration of the manner in which costs of pavement construction, reconstruction and resurfacing vary with use, which suggests that marginal costs of heavy truck use would be very much lower.[22] Once the common cost elements allocated by PCEs — such as the climate-induced deterioration and administration costs — were ignored, marginal costs would also be more than proportionally less for trucks with lower axle weights (for example, for the double-trailer truck than for the straight truck in the these examples). Similarly, once those common elements are ignored, marginal costs would be less on high-volume roads. A pricing regime designed both to be efficient and to recover the fully allocated costs would need a thorough investigation of the relationships between average and marginal costs.

## 5.4 AIR

Unit costs for airport and air navigation services (ANS) were developed by Sypher : Mueller International Inc.[23] from financial data for expenditures associated with airport and aviation infrastructure. Transport Canada expenditures are shown in Table 3(2)-4; related revenues (excluding the Air Transportation Tax) are also included. Some of the costs for, and revenues from, airport property are not attributable to the provision of airport services, and were excluded from the present cost analysis. Costs, as calculated here, are more comprehensive, particularly in including the economic cost of invested capital.

Airport output statistics and cost and revenue data were provided by Transport Canada on a site-by-site basis. The ANS costs were assembled at the national level and were treated as a network, while airport costs were developed on a site-by-site basis. Enroute ANS services provided for the benefit of international flights that do not land in Canada are budgeted separately by Transport Canada, and are almost exactly recovered from specific fees.

### 5.4.1 Airport Cost Allocation

The Royal Commission developed the infrastructure cost attributable to commercial aviation at each of the 98 airport facilities in which Transport Canada has a significant interest. The 98 airports were divided into four groups for which data with varying degrees of cost detail were available.[24]

*Group I — Lester B. Pearson International Airport (Toronto) and Vancouver Airport:* These are the two largest airports in Canada, both in terms of facilities and operations, and are the only sites in Canada that are currently operating at, or near, capacity. As such they have certain distinct asset utilization characteristics and hence cost functions.

*Group II — Remaining major federal airports (MFAs):* The other six MFA sites (Calgary, Edmonton, Winnipeg, Ottawa, Montreal and Halifax) have facilities roughly the same size and all play a similar role in the national transportation system.

*Group III — Sites processing or capable of annually handling 200,000 enplaned/ deplaned (E/D) passengers:* These sites have a minimum level of airfield and terminal facilities that in most cases is adequate to handle volumes of up to a million passengers. The facilities and operations of airports in this group, and their cost behaviour, are generally similar.

*Group IV — Remaining Transport Canada airports:* These facilities are generally small and provide limited services. They have been further subdivided to segregate, in Group IVb, those airports that might be considered "outliers" because of remoteness and/or because the primary orientation may not be toward serving scheduled commercial carriers.

Groups III and IV are referred to as Federally Dependent Airports (FDAs). Fourteen of the airports in Group III used to be accounted for as MFAs; therefore, more detailed data are available for these ex-MFAs. Excluded from these airport groupings were the hundreds of community airports located across Canada. Because these airports are small, do not provide scheduled services, and only limited financial data is available for them, these sites were not included in this study. These airports, however, are an essential link to many small communities.

Direct operating costs, excluding depreciation, were gathered for each site. The cost allocation methodology and data sources and detail varied by airport group. For MFAs, total direct operating costs and operating costs by profit centre were available; this allowed easy removal of costs that were not to be attributed to users. Costs associated with state and military aircraft, as estimated by Transport Canada, were removed from site operating expenses. Also, emergency response service (ERS) costs were attributed strictly to the commercial passenger services and not to other users, such as the Department of National Defence and general aviation.

Costs associated with concession/groundside facilities and industrial areas were available from detailed costing studies that were performed in 1988–89, which allocated a portion of site costs to each of these profit centres. For the 14 ex-MFAs, total direct operating costs and costs associated with concession/groundside facilities and industrial areas were available for 1987–88 from Transport Canada's Financial Projection System, which also allocated a portion of site costs to each of these areas or profit centres.

The direct total operating costs and industrial costs for the remaining FDAs were extracted from Transport Canada's Statement of Revenue and Expenses. Because the financial data recorded for the FDA sites were minimal, a proxy of 10% was used to remove costs associated with concession/groundside facilities. It was further assumed that the industrial profit centre was operated on a break-even basis, and as such, expenses should equal revenue generated. Data were available on industrial rentals, which then served as a proxy for the costs associated with this area.

The Transport Canada allocation of corporate overhead to operating sites was not adopted. No overhead costs were allocated to the eight MFA sites, as they may be considered self-sufficient. These sites have a full complement of management and administrative functions and do not rely on headquarters for support. Therefore, all departmental overhead costs were allocated among the directly managed sites on the basis of direct airfield and terminal operating and maintenance costs.

Airfield costs have been allocated to commercial aviation traffic and to general aviation traffic[25] (other than for-hire transportation) at each airport on the basis of aircraft weight. At congested sites such as the Toronto (Pearson) and Vancouver airports, a movement-based allocation might be argued to be superior, because each movement imposes approximately the same time demands on the facilities and services capacity. A movement-based allocation, however, would be difficult to defend for uncongested airports, since this method assumes that each movement causes the same amount of "wear and tear" on airport assets, regardless of size. A weight base also may be argued to be related to willingness to pay (and to "Ramsey" pricing[26]) and is a more widely accepted and defensible practice for fee setting.

Terminal costs have been measured in relation to the number of passengers enplaned and deplaned. Terminal costs were allocated solely to commercial aviation with the assumption that general aviation makes only minimal use of the terminal building.

Capital infrastructure was included in the cost base on a current replacement value basis (escalated historical cost).[27] As a cross check, the replacement cost based on facility size, for terminal and runway assets, and current construction costs were calculated for a number of sites.

The replacement value was then divided by the 30-year average life of assets on an airport site to determine the annual allocation of past capital investment (depreciation). For ANS assets a 20-year life was used. The opportunity cost of capital component was calculated by multiplying capital replacement value by 50% to get average depreciated value, and then by a real interest rate of 10%.

For the airport system, four basic cost groups were used:

1. Total Commercial Airfield Costs = Commercial Airfield Operations and Maintenance (O&M) Costs + Commercial Airfield Overhead Costs + Commercial Airfield Capital Costs;
2. Total Commercial Terminal Costs = Commercial Terminal O&M Costs + Commercial Terminal Overhead Costs + Commercial Terminal Capital Costs;
3. Total General Aviation (ga) Instrument Flight Rules (IFR) Costs = ga IFR Airfield O&M Costs + ga IFR Airfield Overhead Costs + ga IFR Airfield Capital Costs; and
4. Total ga visual flight rules (VFR) Costs = ga VFR Airfield O&M Costs + ga VFR Airfield Overhead Costs + ga VFR Airfield Capital Costs.

Terminal costs were allocated to the commercial users on the basis of enplaned passengers, and airfield costs at each airport were allocated to commercial users, ga IFR users, and ga VFR users on the basis of their respective weight landed.

A summary of the cost allocation procedure is shown in Table 3(2)-5. Included here are all operations expenses and revenues, net of expenses and revenues attributable to activities that take place on the airport property but do not directly relate to the services Transport Canada provides to the airline and other aviation users of the facilities. Exclusions include industrial developments on the airport property, parking, and retail and refreshment concessions.

### 5.4.2 Air Navigation Services Cost Allocation

Air navigation costs include the cost of air traffic control, flight service stations, and the provision of radio navigation aids. The cost of ANS was divided between local ANS costs and enroute ANS costs. Local ANS costs are the costs of services provided at each airport (for a 50 km radius) while enroute costs are the costs of services provided while an aircraft is between airports.

Operating costs for both local and enroute facilities were derived from data provided by Transport Canada. The data were available in a form that separated local from enroute services and isolated domestic and international enroute services. The international services (polar and oceanic) are near full cost recovery. Thus, both revenues and expenses were excluded from the calculations, leaving a reasonably accurate picture of the costs and revenues of domestic enroute services. These data were also available from Part III of the 1989–90 Estimates,[28] although the detail required to allocate costs to international enroute services for area control centres and flight service stations was not available. As with the airport costing exercise, these accounts represent only direct operating costs and exclude depreciation.

Overhead costs were extracted from Transport Canada's *Proposed New Cost Recovery Policy: Phase II Discussion Paper* (TP 10041). For ease of allocation, overhead comprised ANS regulation costs, ANS safety costs, ANS branch overhead, and an allocated share of Transport Canada's corporate overhead.

Similar to airport capital assets, the value used in the cost base was replacement cost. The replacement value was determined by reviewing the current asset base and known major capital expenditures (such as the current programs of radar modernization and microwave landing systems), and estimating what it would cost to replace these navigation aids. The replacement cost for local and enroute facilities was divided by a factor of 20, which represents the average number of years in the life of ANS capital assets. A cost of capital component was calculated using an interest rate of 10%.

For ANS, as for airports, four cost groups were used:

1. Total Local Commercial and General Aviation (ga) IFR Costs = Local Commercial and ga IFR O&M + Local Commercial and ga IFR Overhead + Local Commercial and ga IFR Capital Costs;
2. Total Local Flight Service Station (FSS) Costs = Local FSS O&M + Local FSS Overhead + Local FSS Capital Costs;
3. Total Enroute Commercial and ga IFR Costs = Enroute Commercial and ga IFR O&M + Enroute Commercial and ga IFR Overhead + Enroute Commercial and ga IFR Capital Costs; and
4. Total enroute VFR Costs = Enroute VFR O&M + Enroute VFR Overhead + Enroute VFR Capital Costs.

Local air navigation services costs were therefore allocated:

| | $ millions (1991) | |
|---|---|---|
| | Local | Enroute |
| Commercial | 137 | 344 |
| General Aviation IFR | 16 | 15 |
| General Aviation VFR | 118 | 75 |

Local costs were allocated to users based on each user's tower arrivals and FSS arrivals. Enroute costs were allocated to users on the basis of domestic total kilometres flown by each group. The resulting cost functions are:

Commercial = \$42.54/movement + \$0.15/km

ga IFR = \$41.16/movement + \$0.15/km

ga VFR = \$82.69/movement + \$1.01/km

Alternatively, the cost attributed to commercial aviation can be allocated on the basis of passengers and passenger-kilometres. To do this, it was first necessary to divide the total among domestic and international services. Cost attributable to overflights that do not land in Canada has already been excluded. For the balance that takeoff and/or land in Canada, to allocate the attributed \$137 million local air navigation services cost, enplanements plus deplanements are estimated as:

| | | |
|---|---|---|
| Domestic | 24 million × 2 × 1.2 stages ⟶ | 58 million E/D |
| Canadian international carriers | | 13 million E/D |
| Foreign carriers (assume) | | 15 million E/D |
| | | 86 million E/D |

This amounts to \$1.60 per passenger per takeoff or landing (1/2 stage).

Enroute costs attributable to commercial aviation of \$344 million may be allocated on the basis of airplane-kilometres under Canadian enroute control, estimated from data on movements and assumptions as to controlled flight length. Itinerant movements in 1990 (Statistics Canada Catalogue No. 51-206, Table 7.1) for commercial carriers are:

| | Movements | Distance |
|---|---|---|
| Domestic | 3,387,000 | 800 kilometres |
| Trans-border | 256,000 | 300 kilometres under Canadian control |
| Other international | 64,000 | 1 000 kilometres under Canadian control |

With the domestic operation accounting for 2.71 billion of a total of 2.85 billion airplane-kilometres, or a share of 95%, enroute costs attributable to commercial domestic operations are $327 million. Allocating over 25 billion domestic passenger-kilometres gives a unit cost of 1.4¢/pass-km.

### 5.4.3 Air Infrastructure Cost (Excluding Land Occupancy)

The final product was the set of cost functions that estimate the unit costs of airport and aviation infrastructure in Canada. By applying the commercial carrier cost model, it was possible to calculate an average cost per passenger from any origin to any destination in Canada.

To calculate the average infrastructure costs applicable to a typical trip, the airport cost function and the corresponding air navigation cost function are used. As an example, consider a trip to Saskatoon from Halifax of approximately 3 500 km, in a B-727 or A320 aircraft with 136 seats, operating at a (system-average) load factor of 0.675, via one intermediate stop (change of flights) at Toronto. The trip thus has two stages, which means two takeoffs and two landings at three airports.

The attributed commercial airlines' costs at Saskatoon, Toronto and Halifax from Table 3(2)-5 give a per passenger airport cost of:

| | |
|---|---|
| Halifax | $ 7 |
| Toronto (two movements) | $12 |
| Saskatoon | $10 |
| | $29 |

Total navigation costs would be:

$6.40 + 3 500 km at 1.4¢ = $55[29]

Not including cost attributable to investment in land, total costs per passenger of air infrastructure services are estimated at $84. Including $20 for the opportunity cost of land in use at the airports, total infrastructure cost becomes $104 per passenger (use of unrounded intermediate data would yield $105).

### 5.4.4 Cost of Land Used for Airports

One can only speculate about the extent and type of development that would take place if the airports were removed from their current sites. Unique mixes of types of use are likely at each of the sites.

An attempt to estimate the opportunity costs of airport land is described in Annex 2 to these Notes. For the nine major airports, potential values as farmland, or in industrial, commercial or residential development are considered.

The areas of land occupied by these airports are very large, and in a number of cases are in locations that would be advantageous for development if the airports were abandoned (or relocated). The areas concerned, however, are so large that they would add substantially to the land available, and could probably only be sold for development at prices below those currently attained for equivalent land.

Indications of potential values of the land at these airports is provided in Table 3(2)-6, based on the following assumptions (described further in Annex 2):

- The sites at Edmonton, Mirabel and Halifax airports are valued as farmland.
- At Calgary, Winnipeg and Ottawa airports, the sites are valued at 25% of the current price for light industrial land.
- For Vancouver and Dorval airports, the available land is valued at 50% of the current price for light industrial land.
- For Toronto (Pearson) airport, the site area is valued at 50% of the current price for residential land.

*Table 3(2)-6*
*Opportunity Costs of Land at Major Airports, 1991*

| Airport | Estimated land values ($ millions) |
|---|---|
| Vancouver | 500 |
| Calgary | 200 |
| Edmonton | 8 |
| Winnipeg | 130 |
| Toronto (Pearson) | 750 |
| Ottawa | 440 |
| Montreal (Dorval) | 400 |
| Montreal (Mirabel) | 10 |
| Halifax | 1 |
| **Total (rounded)** | **2,500** |

The value of those nine major airports is therefore estimated at about $2.5 billion. For the 20 next most important airports, it is assumed that the average value per hectare is half that of these nine airports, excluding Pearson and Vancouver. Their total value would be about $400 million. For all remaining airports, the value of the land is assumed to be negligible.

The total capital value estimated therefore is about $2.9 billion. At a real rate of return of 10%, the annual cost is $290 million per year. Averaged over a total of about 63 million enplaned/deplaned (E/D) passengers at all airports in 1988, the total land value would then amount to $4.60 per passenger. For the illustrative system-wide costs in 1991, this is rounded up to $5 per E/D passenger, or $10 per stage. Averaged over the representative air trip (1.6 stages) of 1 478 km, it amounts to 1.08¢/pass-km (rounded to 1¢/pass-km for system average).

## 5.5 RAIL

The Royal Commission's intercity railway carrier costing is described in Volume 4 of this report.[30] The cost of infrastructure services is shown but there was no cost analysis beyond acceptance of the price

VIA Rail pays the freight railways for track use. Infrastructure payments, including some station rents and incentive payments, which amount to 2.9¢/pass-km, represent only a relatively small proportion of VIA Rail's costs — about 7%. On the per passenger-kilometre basis, however, they are somewhat higher than the estimate of car infrastructure costs and much higher than the estimate of bus costs. Rail track costs are also discussed in the Notes to Chapter 6 in this volume, but without focus on the costing methodology.

The charges VIA Rail pays for track use are closer to being based on a marginal cost concept than on the fully allocated average cost concept used in costing infrastructure for all the other means of passenger transportation.

Payments by VIA Rail to the freight railway track owners for track use and other related services, such as dispatching, signals and communications, are negotiated among the parties — including the Minister of Transport's representative. Should agreement not be reached, however, the fall-back position is long-term avoidable cost as defined by regulations administered and interpreted by the National Transportation Agency. The relationship between CN and CP charges to VIA Rail, and the additional cost that the passenger operation actually imposes on the freight railways, have formed the topic of review by the Canadian Transport Commission and the National Transportation Agency (most recently, the NTA's 1988 *VIA Rail Costing Review*), and a variety of studies by, and for, interested parties including the provincial governments.

The applicable regulations (essentially, the CTC's Costing Order, R-6313) in effect interpret avoidable cost in this case as being long-run variable cost, with respect to track use, including the variable portions of maintenance expense and of capital-related costs — depreciation and cost of capital. Capital-related costs are based on depreciated original cost, historical asset lives, the cost of capital for CP computed in nominal dollars, and an estimated relationship between track maintenance operating expenditures and gross tonnage. As already noted, this differs from the estimate of allocated total cost, with capital treated on a replacement value basis, that was used for the other modes.

It may be of interest to observe that, for rail freight, infrastructure costs generally and the cost of the capital invested in the track infrastructure are much more important relative to total costs than they are for passenger transportation. The 1989 balance sheets for CN and CP[31] show a combined "ways and structures" property investment of over $10 billion at original cost (over $8 billion of it track and roadway), with accumulated depreciation of approximately $3 billion. At a nominal cost of capital of 15% (10% real plus 5% inflation), $7 billion of invested capital represents an annual cost of invested capital of over $1 billion. This equals 20% of 1989 gross freight revenues.

Allocating a pro rata share of this rough estimate of an infrastructure capital charge using the industry rule of thumb — 1 pass-km = one freight tonne-km — would only suggest an $11 million allocation to passenger costs — the equivalent of 0.4¢/pass-km — in 1989. This may be viewed as an indication of the maximum understatement of passenger rail infrastructure costs relative to costs for other modes, as VIA Rail payments would, in principle, already include a capital charge related to a portion of the capital implicitly allocated to it on this pro rata basis.

## 5.6 FERRY

The infrastructure provided for marine ferries not included in vehicle/carrier cost estimates comprises the navigation services and regulatory activities provided by Transport Canada. The amounts of these services provided for the ferries cannot be distinguished readily, as the services are provided jointly for all shipping. Analyses published as part of the development of Transport Canada's cost-recovery policy do not yet provide an allocation of costs to each type of user, but do distinguish attributable costs in 1990–91 for a number of programs.[32] Programs assumed to be used (or provided) in part for ferries are the following (costs include allowances for depreciation and costs of capital):

| | Total costs, 1990–91<br>$ millions |
|---|---|
| Vessel traffic services | 17.46 |
| Short-range navigation aids | 272.98 |
| Safety and public communication | 14.53 |
| Ship safety | 32.66 |
| Emergencies | 25.05 |
| Total | 362.70 |

It is reasonable for illustrative purposes, and in the absence of information on the use of these services by ferries, to allocate the services among various types of commercial shipping according to ship-kilometres travelled in Canadian waters. Using Transport Canada's estimate that ferries account for 11.84%, the amount of the total cost thus attributable to ferries is $42.94 million.

This amount is then distributed between freight and passenger ferry traffic as are the other ferry cost items, according to automobile-equivalent-unit kilometres. The passenger portion is estimated as $35.4 million.

Averaging this cost over the total (non-commercial) passenger-kilometres in 1990 produces a (rounded) 4.5¢/pass-km. When inflated to 1991 dollars, this amounts to 4.7¢/pass-km, which appears in Table 3.1 of Volume 1.

# 6. ENVIRONMENTAL DAMAGE COSTS

## 6.1 EMISSIONS OF AIR POLLUTANTS AND GREENHOUSE GASES

Derivations of costs of emissions are described in the Notes to Chapter 7 in this volume. System-wide averages estimated there (in Table 7(2)-7) are the following (in 1991 prices):

| Means of Travel | Costs (¢/pass-km) |
|---|---|
| Bus | 0.246 |
| Car | 0.577 |
| Train | 0.642 |
| Airplane | 0.921 |
| Ferry | 1.972 |

## 6.2 NOISE

While noise can be an important component of nuisance from all modes, its effects are localized, and greatest in residential locations exposed to high traffic volumes. Most of the noise from intercity passenger travel by road vehicles, trains and ferries is generated away from areas of dense habitation, but airplane noise is a very substantial nuisance close to major airports.

Derivation of an estimate of the cost of airplane noise is also briefly described in the Notes to Chapter 7 in this volume. Valued at $1.00 per passenger-trip system-wide, this noise cost becomes 0.07¢/pass-km over the representative trip of 1 478 km. This is included in the system-average environmental cost for airplane travel in Table 3-1 of Volume 1 and Table 3(2)-1.

No costs are included for noise in any of the other modes, partly because research has not provided comparable estimates for intercity travel by the other modes, and partly because it is expected that such costs would be very small in relation to the other cost estimates and their ranges of uncertainty.

## 7. ACCIDENT COSTS

The derivation of costs of damage in accidents is described in the Notes to Chapter 8 in this volume. Minimum losses per victim are estimated, from research on road accidents, as $330,000 per fatality and $10,000 per person injured, in 1990 prices. The alternative value of the losses per fatality, adopted recently by Transport Canada after researching individual willingness to pay for risk reductions, amounts to $1.5 million, in 1991 prices. That value has been adopted in the costing by mode that follows, together with $10,000 per person injured, where relevant.[33]

### 7.1 CAR ACCIDENT COSTS

The value for the social losses in all road accidents based on the Transport Canada values per casualty, together with estimates of other property damage losses, is estimated in Chapter 8 at about $14 billion, in 1991 prices.

To be compatible with the estimates of infrastructure costs, an estimate is needed of the amount of these losses that takes place on the paved provincial highway system. National road accident statistics show that some 65% of deaths and 30% of injuries were on roads with speed limits greater than 60 km/h. Those injuries and property damage accidents occurring on highways, however, are likely to be much more severe than the average (occurring at higher average speeds), and therefore to cost substantially more than the average.

The statistics also fail to show what proportion of highway accidents involves passenger vehicles. Strictly, deductions should be made for the losses attributable to non-passenger vehicles. The most important other group of vehicles is heavy trucks, because of their over-involvement in severe casualties. Available statistics show them to be involved in about 3% of all accidents, and about 9% of deaths. But no information is available to determine responsibility for those accidents and casualties.

The simple assumption is made that 55% of the total accident damage cost is on highways and attributable to passenger vehicles, or a total of about $7.7 billion per year. Given its uncertainty, this figure is rounded to $8 billion. Averaged then across 210 billion total passenger kilometres by these vehicles, this would amount to about 3.8¢/pass-km. This figure appears in Table 3-1 of Volume 1 as the "total accident" cost for car travel.

Of this total amount, there is a proportion of health care costs for road accident victims that is not recovered from motor vehicle insurers, but borne instead by others. This is estimated in the Notes to Chapter 8 in this volume as about $300 million in total in 1990. Using the earlier assumption, 55% or $165 million of this would be attributed to highway passenger traffic. Averaging this over 210 billion passenger kilometres and inflating gives 0.082¢/pass-km in 1991 prices, which appears (suitably rounded) in the relevant cell in Table 3-1 of Volume 1.

The remainder of the 3.8¢/pass-km in losses is user borne, or 3.7¢/pass-km in the rounded figures of Table 3-1.

It should be noted that these estimates may conceal a large element of non-monetary cost, which is borne by the victims of accidents without compensation. (Monetary costs include loss of earnings as a result of death or injury.) Of the amounts estimated earlier to be borne by users, the largest part is borne in costs of accident insurance and the deductible amounts of damage claims paid personally by vehicle owners. However, being based on "willingness to pay," the estimates include a large portion that would represent non-monetary damage in accidents — remembering that monetary damage losses sum to only about $9.5 billion in 1991 prices. The other $4.5 billion can be characterized as representing instead the emotional losses. If 55% of these occur in highway accidents, they amount to about $2.5 billion. These losses are probably not compensated fully, if at all, by those responsible for the accidents, or their insurance companies. The amount concerned is unknown, as the extent of compensation from insurance companies or directly from responsible owners/drivers is not recorded.[34]

It should be further noted that some part of those emotional losses are actually borne by non-users of motor vehicles — essentially pedestrians and bicyclists — in highway accidents (it being assumed that their monetary losses are compensated from insurance and health care systems). As these groups constitute about 15% of all road accident fatalities, they might account for 15% of the total emotional losses. The amount might be substantial compared with many of the component costs borne by non-users in Table 3-1. If total emotional losses were as great as $2.5 billion, and if 15% of that was borne by non-users of motor vehicles it would be close to $400 million. The amount is more likely some fraction of this. Any estimate would be entirely conjectural, however, so this cost has not been distinguished in the tables, and remains within the estimate of user-borne accident costs.

## 7.2 BUS ACCIDENT COSTS

The fatality rate in passenger operations is estimated in the Notes to Chapter 8 in this volume, from the (very sparse) information available on intercity bus accidents from Transport Canada, as 2.0 per billion passenger-kilometres. If Transport Canada's guidance of $1.5 million per death avoided is applied to these, a total of $3 million per billion passenger-kilometres, or 0.3¢/pass-km is obtained.

The accident statistics also show that the ratio of injured victims to fatalities was about 38 (265 injured versus 7 killed in the sample of jurisdictions and years considered). Applying Transport Canada's cost of $10,000 per injured victim, the ratio of injury cost to fatality cost would be 0.20. Adding the injury cost to the fatality cost produces a combined cost of 0.36¢/pass-km.

Finally, an approximate allowance for property damage can be made, in the absence of statistics on the incidence of property damage accidents involving intercity buses, from the observation that the total costs estimated for property damage in road accidents amounts to about two thirds of the total costs of injuries. Adding this proportion would bring the system-average bus accident costs up to 0.4¢/pass-km.

Of this cost, some small amount would be borne by non-users, for similar reasons as for car accident costs. The amounts would probably be similar in proportion — about 2% of accident costs, or in this case only 0.008¢/pass-km. The relevant cell in Table 3-1 therefore shows 0.0¢/pass-km.

## 7.3 AIRPLANE ACCIDENT COSTS

For levels 1 and 2 carriers, the average fatality rate over the decade to 1990 is estimated in the Notes to Chapter 8 in this volume as 0.13 deaths per billion passenger-kilometres. At $1.5 million per fatality, that amounts to only 0.0195¢/pass-km.

The uncertainty of the fatality rate is underlined, however, by the fact that if the Nationair crash at Jeddah in 1991 is included the decade's fatality rate would change to 0.60 per billion passenger-kilometres, in which case, the cost would be about 0.09¢/pass-km.

The cost of injuries and property damage should be added to these costs. In air crashes, injuries are not numerous enough compared with fatalities to make much difference to the estimated cost. No estimates of the extent and costs of property damage in passenger aircraft accidents in Canada are available, but the price of passenger-carrying airplanes suggests that it could be significant. On the other hand, the average cost is unlikely to be as much as that estimated for the victims; at Transport Canada's value of $1.5 million per person, even the most expensive modern airplane is worth less than its passengers.

In summary, it is concluded that the true cost of airplane accidents is unlikely to exceed 0.1¢/pass-km, which is the value used in the illustration.

As with bus accident costs, the amount of these air accident costs borne by non-users is expected to be so small that the relevant cell of Table 3-1 appears as 0.0¢/pass-km.

## 7.4 TRAIN ACCIDENT COSTS

The estimates in the Notes to Chapter 8 in this volume show the rate of all fatalities involving passenger trains over the decade to 1990 as 13.8 per billion passenger-kilometres. The great majority of these deaths were to motor vehicle users at grade crossings or people walking on the rail lines (including suicides). The question arises whether their costs should be attributed as a social cost of rail transport. In nearly all such cases, the railway is not legally at fault; though the deaths would clearly not have occurred in the absence of the trains. This issue is not resolved here, but for the illustrative costs, none of the costs of these other victims has been attributed to the train.

Deaths to passengers and rail employees in passenger operations, which are therefore assumed to be attributable to train travel, occurred at a rate of 1.16 per billion passenger-kilometres over the decade. Valued at Transport Canada's average of $1.5 million, the cost of these deaths amounts to 0.17¢/pass-km, in 1991 prices. To this should be added the costs of those passengers and employees injured in these accidents.

In the absence of details of the numbers injured in passenger operations during the decade, some indication of the long-term relationship between numbers killed and injured can be gained from the statistics for all main-line railway accidents, which show a ratio of 27 injured for each death (976 injured compared with 36 killed over the decade). Using Transport Canada's road accident costs of $10,000 per average injured victim, this would add $270,000, or 18%, to each $1.5 million in costs of fatalities. This would raise the estimated system-average accident cost to 0.20¢ per pass-km.

The amount borne by non-users is again not zero, but expected to be so small that the relevant cell of Table 3-1 appears as 0.0¢/pass-km.

### 7.5 FERRY ACCIDENT COSTS

The fatality rate in ferry operations is estimated in the Notes to Chapter 8 in this volume as 0.5 deaths per billion passenger-kilometres. It is assumed that injuries are insignificant compared with deaths, as most deaths are by drowning (and given the differences in the average costs per victim injured and killed).

Valued at Transport Canada's cost of $1.5 million per person killed, the accident costs amount to 0.075¢/pass-km, which is quoted in Table 3-1 as 0.1¢/pass-km. Once again, the non-user portion is not zero, but negligible in Table 3-1.

## 8. VEHICLE/CARRIER COSTS AND SPECIAL TRANSPORTATION TAXES/FEES

### 8.1 CAR

As described in Volume 1 of this report, the term "car" is used as a shorthand reference for all private passenger vehicle use, most of which is in passenger cars, but with a significant proportion being in light trucks (30 billion passenger-kilometres, of a total on the "highway" system of 210 billion, or about 14%). Light trucks are mostly pickup trucks and passenger vans — defined as under 10,000 lb. (4 550 kg) laden weight, but nearly all under 6,000 lb. (2 725 kg) laden. Their cost characteristics are somewhat different from those of passenger cars; therefore, it is necessary to estimate costs for an average vehicle, blending costs for cars and light trucks in proportion to their use.

A report for the Royal Commission provided estimates of the costs of vehicle ownership and operation separately for cars and light trucks. Of these costs, insurance costs are included within user-borne accident costs, and vehicle licence costs and fuel taxes are included as special taxes/fees. Vehicle/carrier costs consist of the remaining costs of vehicle ownership and use. Costs for maintenance, depreciation and cost of capital are shown in Table 3(2)-7.[35] Estimates summarized in this table were provided for 1990 and are inflated to 1991 prices in the final column. The combined average figures weight the use of cars and light trucks by their total passenger-kilometres.

*Table 3(2)-7*
*Average Unit Costs: Cars and Light Trucks*

| | $/veh per year (1990) | ¢/veh-km (1990) | ¢/pass-km (1990) | ¢/pass-km (1991) |
|---|---|---|---|---|
| **Cars** | | | | |
| Maintenance | 409 | 2.3 | 1.3 | 1.4 |
| Depreciation | 1,230 | 7.0 | 3.9 | 4.1 |
| Cost of capital | 1,020 | 5.8 | 3.2 | 3.4 |
| **Light trucks** | | | | |
| Maintenance | 409 | 2.3 | 1.5 | 1.6 |
| Depreciation and cost of capital | 2,030 | 11.3 | 7.5 | 7.9 |
| **Average passenger vehicle** | | | | |
| Maintenance | 409 | 2.3 | 1.3 | 1.4 |
| Depreciation and cost of capital | 2,210 | 12.6 | 7.2 | 7.5 |

The cost of fuel is estimated for mid-1991 from a national average price (weighted by sales) of 55¢/L of gasoline, together with approximate average highway fuel consumption of 9 L/100 km for cars and 12 L/100 km for light trucks, together with average highway car occupancy of 1.8 passengers and light truck occupancy of 1.5 passengers. The cost for cars is 55/(100/9) = 4.95¢/veh-km, and 4.95/1.8 = 2.75¢/pass-km, and for light trucks 55/(100/12) = 6.6¢/veh-km, and 6.6/1.5 = 4.4¢/pass-km. Combined in proportion to passenger-kilometres driven, the blended average "car" fuel cost is 2.95¢/pass-km.

From this cost of fuel, the amount paid as special tax is deducted, and then appears as part of the "special tax/fee" item in the system average cost table instead of as a "vehicle/carrier" cost component. The relevant amount of tax is defined to be the amounts of provincial and federal taxes on gasoline in excess of the normal amounts of sales taxes charged in the jurisdictions concerned. The calculation is documented in Table 3(2)-8.

The federal excise tax of 8.5¢/L is included as part of the special charge for use of transport, but not the federal GST. Quebec's defined provincial excise tax is included without adjustment. In all other provinces, a motive fuel tax is charged instead of the normal provincial sales tax. Subtracting the amount that could have been charged as provincial sales tax leaves the component of the special charge for use of transport. The total of these charges averaged 17.8¢/L in 1991, when weighted by fuel use by province. Using the assumption of 9 L/100 km for cars, this special tax is therefore 1.6¢/veh-km, or 0.89¢/pass-km. For light trucks using 12 L/km it is 2.14¢/veh-km or 1.42¢/pass-km. The blended average for car is 0.95¢/pass-km. When combined with licence fees, which average 0.22¢/pass-km (see subsection 5.1.4), the total special transportation tax/fee for cars is thus rounded to 1.2¢/pass-km.

It is estimated that the net amount of fuel cost to be included in vehicle/carrier cost is, therefore, 2.95–0.95 = 2.0¢/pass-km. Total vehicle/carrier cost is the sum of the amounts estimated earlier for maintenance, depreciation and cost of capital, and fuel, or 1.4+7.5+2.0 = 10.9¢/pass-km (rounded) at 1991 prices.

*Table 3(2)-8*

## FUEL TAX RATES PER LITRE: 1991 AVERAGE

| | British Columbia | Alberta | Saskat-chewan | Manitoba | Ontario | Quebec | New Brunswick | Nova Scotia | Prince Edward Island | New-foundland | Canada Average |
|---|---|---|---|---|---|---|---|---|---|---|---|
| **Federal Excise** | | | | | | | | | | | |
| Gasoline | 8.5 | 8.5 | 8.5 | 8.5 | 8.5 | 8.5 | 8.5 | 8.5 | 8.5 | 8.5 | **8.5** |
| Road diesel | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | **4.0** |
| Aviation turbo | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | **4.0** |
| Locomotive | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | **4.0** |
| **Provincial Special Tax — In Excess of the Standard Sales Tax Rate** | | | | | | | | | | | |
| Gasoline | 7.3 | 8.4 | 7.6 | 7.3 | 9.4 | 11.9 | 7.3 | 8.0 | 7.2 | 7.5 | **9.3** |
| Road diesel | 7.8 | 8.5 | 7.3 | 8.1 | 9.0 | 10.5 | 8.3 | 10.5 | 7.6 | 9.0 | **9.1** |
| Aviation turbo | 1.5 | 5.0 | 5.1 | 3.9 | 0.2 | 3.0 | -1.4 | -2.5 | -2.7 | -3.4 | **1.8** |
| Locomotive | 1.5 | 9.0 | 13.1 | 11.7 | 2.0 | 3.0 | 0.9 | -3.1 | 9.0 | -3.7 | **5.5** |
| **Total Special Taxes — Federal plus Provincial** | | | | | | | | | | | |
| Gasoline | 15.8 | 16.9 | 16.1 | 15.8 | 17.0 | 20.4 | 15.8 | 16.5 | 15.7 | 16.0 | **17.8** |
| Road diesel | 11.8 | 12.5 | 11.3 | 12.1 | 13.0 | 14.5 | 12.3 | 14.5 | 11.6 | 13.0 | **13.1** |
| Aviation turbo | 5.5 | 9.0 | 9.1 | 7.9 | 4.2 | 7.0 | 2.6 | 1.5 | 1.3 | 0.6 | **5.8** |
| Locomotive | 5.5 | 13.0 | 17.1 | 15.7 | 6.0 | 7.0 | 4.9 | 0.9 | 13.0 | 0.3 | **9.5** |

## 8.2 INTERCITY BUS

To generate the system-average costs of intercity passenger bus in Table 3-1 and the illustrative route examples of Tables 3-2, 3-3, 3-4 and 3-5, a simple method based on published data[36] was used.

| | ($ millions) |
|---|---|
| For classes 1 and 2: | |
| Taking operating expenses minus | 316.4 |
| bus depreciation expense | – 14.4 |
| equals: | 302.0 |
| Attributing an estimated 75% to intercity | × 75% |
| passenger unit toll services gives: | 227 |
| Adding approximate average replacement-value-based depreciation and cost of capital ($32,000 multiplied by 1,273 buses) | + 41 |
| equals the total for classes 1 and 2 | 268 |
| For total activity: | |
| Prorating for the intercity unit toll services of operators other than classes 1 and 2 (an additional 273 million pass-km or 8.3%) results in: | 290 |
| Allowing for a reduction in the level of activity from 1989 to 1991, in line with the long-term trend (2 years at –2.9%) provides: | 274 |
| Inflating 1989 dollars to 1991 dollars (2 years at 4.5%) gives a final total of: | 299 |

This figure, $299 million, is the total to be found under users in Table 3-1(b). Divided by the estimate of 3.3 billion passenger-kilometres, it implies a system-average users cost of 9¢/pass-km.

The special tax/fee for bus travel consists of fuel tax and vehicle licence fees. Fuel use is estimated by Royal Commission staff to average 0.405 L/bus-km, or 0.019 L/pass-km with average occupancy of 45%. Federal and provincial special taxes on diesel fuel, in excess of normal sales taxes, averaged 13.1¢/L in 1991. The average fuel tax was therefore 0.25¢/pass-km.

Provincial vehicle licence fees for intercity buses average about $500 per year,[37] or less than $0.5 million in total for about 1,000 buses engaged in intercity scheduled services in Canada. Averaged over 160 000 km per bus per year, the fee is less than 0.6¢/veh-km and at 45% occupancy is therefore 0.015¢/pass-km. Adding together fuel tax and licence fees gives a rounded average of 0.3¢/pass-km.

In considering the possible relaxation of economic regulation of the intercity bus industry (discussed in Chapter 13 of Volume 1), it was desirable to assess the importance of cross subsidization across different route types under the current regulatory regime. For this purpose, a much more detailed study of intercity bus carrier costing was undertaken; this study by Lake et al. is included in Volume 4 of this report.[38]

Two cost formulas were developed to reflect the differences between the major, large-scale carriers and the small-scale, often remote carriers. These formulas were based on cost and statistical data made available to Royal Commission staff on a confidential basis by various bus operators. For the study of cross subsidization within the intercity scheduled bus industry, the formulas were applied to a sample of actual routes, and the results examined as reported in Lake et al.

This method introduced output units into the costing, which allowed the cost characteristics of different types of routes to be captured. The usual measure used by the bus industry for cost analysis is the bus-mile.[39] However, for the analysis of cross subsidization, cost categories were attributed according to a notion of the relationship to bus-miles: using bus hours to reflect the different time to distance ratios of some services, and a per-passenger element to reflect costs that are variable with the volume of traffic (number of passengers) but not with distance travelled. For most cost categories, there was insufficient consistency among the accounting definitions used by the various carriers to justify basing an estimate on averages. Rather, cost components from different sources were blended to achieve unit costs that appeared to represent a typical or normal level of cost.

Replacement value based depreciation and cost of capital charges for buses were included in the bus-hour cost:

| | |
|---|---|
| Cost of new bus (1989–1990) | $260,000 |
| Average life | 10 years |
| Cost of 5-year-old bus | $100,000 |
| End of life salvage | $20,000 |
| Depreciation | straight line |
| Real cost of capital | 10% |

This results in an ownership cost per year for a new bus (assumed for the large-scale operations) of $38,000, and for a five-year-old second-hand bus (assumed for the small-scale operations) of $22,000. The unit cost reflecting bus time was calculated per scheduled bus hour. This made calculation of the cost for specific services easier, because the cost includes an idle or utilization factor. Analysis indicated that there are between three and a half and five buses owned for every one actually moving and carrying passengers on scheduled service at an average point in time. Overall, it was estimated that, for every hour that a bus is moving with passengers, it has spent or will spend more than three and a half hours in terminals, in a garage, or available for service. This factor was calculated using bus inventory, bus mileage and an estimate of average schedule speed of 40 or 50 mph (65 to 80 km/h). It only provided a rough approximation, but data required to make more dependable estimates were not available.

The calculated cost per passenger included a cost for terminals that represents terminal charges or rent (based on data from carriers that rent terminals). Some carriers own all of the terminals they use, some do not own any. Most of the large carriers own some terminals and pay charges or rent for the shared or exclusive use of others. The owners of at least one major carrier own a terminal that is treated as a separate profit centre, charging the bus operation for its use.

The data were combined in an effort to present a reasonable approximation of the industry cost structure without disclosing data for any single contributor. It proved impossible to mask fully the costs of one or more of the large carriers; thus, only the qualitative conclusions, and not the specific cost estimates have been included in the study. The estimates could be used without endangering confidentiality, however, to develop differentials by which costs calculated for types of routes — used in the sample route tables of Chapters 3 and 18 of Volume 1 — differed from the system-average costs and fares outlined at the start of this section and presented in Table 3-1 of Volume 1.

## 8.3 AIRPLANE

The unit-cost development was based on an analysis of system data designed to allow some recognition of factors that contribute to differences in costs of different types of flights.

The analysis, however, does not consider network size or configuration, or a number of other reasons why marginal cost, or the cost of domestic services isolated from international operations, might depart markedly from the unit-cost estimates.

The estimates are based on 1989 data and a 1989 industry; in the case of the Level 1 carriers some modifications were made as later data became available. It may be noted that several of the carriers included in the data for independent jet carriers were, as of 1991, no longer operating. Developing an estimate of total air carrier costs for domestic services from the costs for a typical domestic air journey, however, avoids any biases that this might have created.

The air service costing was based on data provided by Statistics Canada, supplemented with information provided by airlines. These were allocated according to operational relationships, making use of a number of earlier studies.[40] This process benefited from the comments of Air Canada, Canadian Airlines International and the Air Transport Association of Canada.

The airlines' cost data do not separate freight from passenger operations. To the extent that passenger seats and (belly) freight capacity are jointly produced, separation for the present analysis was arbitrary. Because the purpose of the exercise was to develop passenger costs, and because freight carried by carriers represented approximately 10% of revenue, costs for Level 1 were reduced by 5%, presuming that one half of the freight was carried in belly space. Freight was not considered for carriers other than Level 1.

Air services available to passengers in Canada vary from single-engine charter float-planes to trans-Atlantic and trans-Pacific direct flights in B-747 aircraft with more than 450 seats. Scheduled carriers, Levels 1 to 3, account for 97% of Canadian carrier costs. The costing was performed separately for the Level 1 carriers (Air Canada and Canadian Airlines International), a sample of independent jet carriers (Nationair, Quebecair, Soundair, Worldways, Canada 3000, Execair, Holidair and Vacationair) and a sample of turboprop connectors or commuter carriers (Air Alliance, City Express, Ontario Express, Air Atlantic and Air Ontario).

Instead of the more conventional, strictly time-based approach, expense data were adjusted to remove aircraft depreciation expense and rentals, supplemented by a replacement value aircraft capital recovery charge at an interest rate of 10%, and attributed to four output units:

- seat-kilometres;
- seat-stages;

- passenger (same airplane) flights; and
- passenger trips.

The cost allocation for the Level 1 carriers for 1991 (1989 data adjusted to 1991 cost levels) is shown in Table 3(2)-9 on the following page. The table is based on costs of all passenger services, international and domestic. Treatment of the other carrier categories is briefer.

Although recent years have seen considerable fluctuation, an average load factor of 67.5% was taken — from Air Canada and Canadian Airlines International (PWA Corporation) annual reports — as representative of sustainable performance in this regard. Revenue passenger-kilometre, seat-kilometre, passenger-flight, revenue-passenger and other intermediate output units such as average stage,[41] flight and trip lengths (as estimated from Statistics Canada data, data provided by the airlines and airlines' annual reports[42]) allowed estimates of the necessary output units.

Unfortunately, the data did not always appear consistent. This imprecision, however, was not greater than that of the overall costing exercise and should not compromise the results. The uncertainty included average flight length and passenger-trip length; Statistics Canada counts flight coupons and hence overestimates trips where there are changes of planes. Estimates of an average 1.15 aircraft stages per flight and 1.16 flights per passenger trip[43] were based on data from Statistics Canada Catalogue No. 51-206, Table 2.3 and airline data; the Statistics Canada's Canadian Travel Survey[44] reported the 23 million passengers handled.

Flight-crew costs are allocated on the basis of flying hours. The literature (cited earlier) included regressions of Canadian airlines' turbojet flight time against distance. The regression selected (Moloney, 1985) was the most comprehensive. Flight-time estimates were calculated as a constant of 0.4006 hours per stage plus 0.0020 hours per mile. It is further noted that crew costs vary with aircraft type; smaller airplanes (that typically operate on shorter stages) generally have higher crew

Table 3(2)-9

COST ALLOCATION, PASSENGER SERVICE, LEVEL 1 AIR CARRIERS, 1989 (1991$)

| | | Seat-km | | | Seat-stages | | | Passenger flights | | | Passenger trips | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| **Output Units (millions)** | | 75,000 | | | 46 | | | 27 | | | 23 | | |
| | **Expense** | **Alloc-ation** | **Total** | **Per unit** | **Alloc-ation** | **Total** | **Per unit** | **Alloc-ation** | **Total** | **Per unit** | **Alloc-ation** | **Total** | **Per unit** |
| **Air Operations** | | | | | | | | | | | | | |

| Flight crews | 327.1 | 73% | 238.7 | 0.00319 | 27% | 88.3 | 1.94 | | | | | | |
| Landing, insur. | 516.0 | | | | 100% | 516.0 | 11.32 | | | | | | |
| **Air Maintenance** | | | | | | | | | | | | | |
| Labour | 206.6 | 44% | 90.9 | 0.00122 | 56% | 115.7 | 2.54 | | | | | | |
| Materials, other | 425.5 | 44% | 187.2 | 0.00250 | 56% | 238.3 | 5.23 | | | | | | |
| **In-Flight Services** | | | | | | | | | | | | | |
| Cabin crews | 287.5 | 57% | 163.9 | 0.00219 | 43% | 123.6 | 2.71 | | | | | | |
| Food, supp, other | 428.1 | 50% | 214.1 | 0.00286 | 40% | 171.2 | | 10% | 42.8 | 1.60 | | | |
| **Terminal** | 942.0 | | | | | | | 60% | 565.2 | 21.12 | 40% | 376.8 | 16.38 |
| **Marketing** | 1,043.0 | | | | | | | | | | 100% | 1,043.0 | 45.35 |
| **Air Capital** | 512.8 | 44% | 225.6 | 0.00302 | 56% | 287.2 | 6.30 | | | | | | |
| **Total** | **5,750.6** | | | **0.02521** | | | **36.55** | | | **22.72** | | | **61.73** |

costs per seat-stage and seat-kilometre. The analysis did not allow for this.

Fuel was attributed to flight hours, with a small allowance for taxiing. Cabin-crew costs were allocated on the basis of flying hours plus 40 minutes per stage. Maintenance cost and the physical wear of a turbojet airplane are attributed partially to cycles (takeoff, pressurization, de-pressurization, landing) and partially to flying hours. A figure of 40% attributable to cycles (Aviation Planning Associates, 1983) yields estimates of 44% attributable to seat-miles and 56% to seat-stages.

Because most airplane accidents occur at takeoff or landing, insurance, with landing fees, was attributed entirely to these activities. For terminal costs, the only data found that matched the definition used here were old (Bajwa and Shurson, 1981). These were escalated using an approximate construction cost index.

The cost aggregate termed "marketing" includes travel agents' commissions that are generally paid as a percentage of revenue. Using this would introduce a further output unit; however, at the basic level (cost to the agent), passenger-trips would seem a reasonable variable. General and administrative cost, presumably relating to corporate administration, was allocated to all of the preceding items.

Computations for levels 2 and 3 are similar. To convert costs per seat-mile into figures appropriate for comparisons, an average load factor of 67.5% was applied to the Level 1 data. For the connectors/commuters it was estimated as 56%, and for the independent (charter) jet carriers where load factor data were not available, 80% was assumed. It is noted that, perhaps more than any other parameter, the assumption of a uniform load factor distorts route and service comparisons.

System-average costs are calculated by service type as shown in Table 3(2)-10.

*Table 3(2)-10*
*AIR CARRIER AVERAGE UNIT COSTS (IN 1991 DOLLARS)*

| | **Passenger-kilometre ($)** | **Passenger-stage ($)** | **Passenger-flight ($)** | **Passenger-trip ($)** |
|---|---|---|---|---|
| Level 1 | 0.0373 | 54.15 | 22.72 | 61.73 |
| Commuter | 0.0961 | 39.50 | 8.73 | 17.28 |
| Charter jet | 0.0467 | 62.81 | 10.91 | 13.97 |

As an example, the computed average per-passenger cost for a trip from Saskatoon to Halifax (Level 1 carrier) with a change of airplanes in Toronto would be:[45]

| | | |
|---|---|---|
| 3 500 km | at $ 0.0373 | $130.55 |
| 2 stages | at $54.15 | 108.30 |
| 2 flights | at $22.72 | 45.44 |
| 1 trip | at $61.73 | 61.73 |
| | | $ 346.02 |

### 8.3.1 System-Average Domestic Air Trip, 1991

Statistics Canada and the airlines do not keep cost and revenue data for domestic travel. It would not be logical to attempt to keep accounts under that structure; domestic, Canada–United States and international services are operated as an integrated network. The cost characteristics of the different services are, however, quite different. The overseas international services with long average flight and stage lengths, using larger aircraft, differ particularly. To estimate domestic-system-average and system-total costs, a typical trip of 1 478 air kilometres was defined as indicated by Statistics Canada's and other available data. It is noted that these data on flight characteristics are for all airlines (Levels 1 to 3) and for domestic services in isolation; however, the system-average-cost estimate is based on Level 1 carrier cost factors.

|  |  |  |  |
|---|---|---|---|
| Computed carrier cost | 1 478 kilometres | at $0.037 | $55 |
|  | 1.6 stages | at $54 | 86 |
|  | 1.4 flights | at $23 | 32 |
|  | 1 trip | at $62 | 62 |
|  |  |  | $235 |

This yields an average cost of 15.9¢/pass-km to which another $20, or 1.4¢/pass-km, Air Transportation Tax may be added — for a total of 17.3¢/pass-km. The average ticket yield was, however, estimated to be $222 for a trip of this length[46] (15¢/pass-km), or $242 (16.4¢/pass-km) with the Air Transportation Tax. These estimates suggest that the airlines are operating at a loss of 0.9¢/pass-km if one includes a return on capital invested in aircraft.

While these estimation methods are not precise, in the short run it is true that losses are being incurred. It is not, however, reasonable to expect such a condition to persist for very long. To model a more representative steady state condition, it was assumed that the difference will ultimately be made up through price increases averaging approximately 6%.

Special tax/fee costs for air travel consist only of the applicable fuel tax. Royal Commission staff estimate that average fuel consumption for domestic air services is 0.103 L/pass-km. The special tax rate applicable to aviation turbo fuel was 5.8¢/L in 1991. The average tax was therefore 0.6¢/pass-km.[47]

## 8.4 RAILWAY PASSENGER

For practical purposes, when one considers the cost of railway passenger services in Canada, one may limit the consideration to VIA Rail. VIA Rail accounts for 95% of the industry's passenger-kilometres, and the other carriers' unit costs are of the same general order as VIA Rail's. As well, since VIA Rail is exclusively a passenger carrier, no separation of freight from the passenger operations is required in analyzing its data.

The Royal Commission's intercity rail-carrier costing is described in Volume 4 of this report.[48] For the most part, the service costing was based upon VIA Rail's 1990 year-end results. Data for 1989 were available and were used in circumstances where the substantial service rationalization that occurred in January 1990 would have distorted the 1990 results, making them unrepresentative of the longer term.

Overheads and indirect costs included: functional overheads, general corporate overheads, shared facilities and operations, plus the cost of capital on equipment and facilities. The costs used for the year 2000 status-quo costs of Chapter 18 are steady-state in the sense that allowance has been made for improvements in the cost experience of passenger rail.

System-total data for 1991, as shown in Table 3-1 of Volume 1, were estimated from recently available 1991 VIA Rail data, plus escalated 1987 data for BC Rail, and the Algoma Central, Ontario Northland and Quebec North Shore and Labrador Railways. Total Canadian railway passenger revenues and costs, and VIA Rail's share, are:

| | $ million (1991) | | |
|---|---|---|---|
| | VIA Rail | Other | Total |
| Passenger revenue | 144 | 10 | 154 |
| Operations subsidy | 353 | 38 | 391 |
| Depreciation and cost of capital[49] | 62 | included | 62 |
| Total | | | 607 |

Special tax/fee costs for train travel consist of the fuel taxes paid that would be in excess of the normal sales taxes. Average fuel consumption was estimated by Royal Commission staff as 0.043 L/pass-km. Combined with the average special tax-rate on locomotive fuel of 9.5¢/L in 1991, the tax amounted to 0.4¢/pass-km.

## 8.5 FERRY

Cost estimates are based on a research report to the Royal Commission.[50] The report provides cost, revenue and traffic records for the three major ferry corporations: British Columbia Ferry Corporation, Marine Atlantic Inc. and Northumberland Ferries Ltd., which together provide about 95% of Canada's total ferry passenger-kilometres. Estimates of average costs and revenue per passenger-kilometre are developed for these three operations combined and used to represent all domestic intercity ferries. Other intercity services included are the Central Region Ferries in the Great Lakes (Tobermory to South Baymouth) and St. Lawrence (Matane to Godbout; Matane to Baie Comeau; Rivière du Loup to St. Siméon; Trois Pistoles to Les Escoumins), and the Atlantic region service from Souris to the Magdalen Islands. On the other hand, limiting the focus to domestic services means that the service by Marine Atlantic between Yarmouth and Bar Harbor is consequently excluded, as are services such as Victoria to Seattle, Sidney to Anacortes, Victoria to Port Angeles and Yarmouth to Portland.

Costs and revenues are for the fiscal year 1990-91, but are assumed adequate to represent 1991 conditions and 1991 prices. Capital charges were estimated including depreciation and a capital charge on the remaining value of the assets, in a manner similar to that described for air infrastructure. Costs and revenues were estimated per passenger-vehicle-kilometre; that is, vehicle-kilometres by passenger vehicles, as opposed to trucks. These were distinguished by allocating the costs between freight vehicles and passenger vehicles on the basis of space used by the vehicles, measured in "automobile-equivalent" units (an average heavy truck being about three automobile-equivalents). The resulting estimates are:[51]

|  | Costs | Revenues |
|---|---|---|
|  | ($/passenger-vehicle-kilometre) |  |
| BC Ferries | 0.91 | 0.76 |
| Marine Atlantic | 1.98 | 0.85 |
| Northumberland Ferries | 2.28 | 1.01 |

### 8.5.1 Exclusion of Food Services and Other Merchandise Retailing

As for the other modes (in particular airports), costs and revenues attributable to commercial activities other than providing passenger service, and not included in the ticket price, were subtracted from the ferry data. This included cost and revenue related to catering services and other sales of goods. The accounts provided for BC Ferries and Marine Atlantic offer the relevant information (for the former, "cost of food and goods sold" and "catering and other income"; for the latter, "vessel services revenues"). The calculation, in fact, deducts revenue rather than costs, on the assumption that the revenue recovers not only the costs of the materials concerned, but also an appropriate proportion of crew and vessel costs. (This is a tenuous assumption, which probably overstates the costs concerned and so produces a slight underestimation of the remaining transportation costs.)

The arithmetic of removing catering and other sales was:

- For BC Ferries, to estimate them as a proportion of the "ships" costs, and to deduct this proportion from the "vessels" costs per passenger-vehicle-kilometre;
- For Marine Atlantic, to estimate them as a proportion of the "vessels" expenses, and to deduct this proportion from the "vessels" costs per passenger-vehicle-kilometre; and
- For Northumberland Ferries, no information on such costs was available and no deduction was made.[52]

### 8.5.2 Exclusion of Excess Vessel Costs Arising Through Local Construction

Capital cost estimates, and thus total vessel costs, were modified to remove the excess amount incurred through purchasing local construction, as opposed to the lowest-cost (off-shore) alternative. This modification of the estimates of costs is in accordance with the Royal Commission's intention that costs incurred by government in pursuit of non-transportation goals be charged to general revenues — implying that those vessel costs arising from an intention to support Canadian shipbuilders, beyond a level provided by standard import tariffs, should not be included in the costs that users are asked to pay.

The amounts of vessel costs concerned can be estimated only very approximately. From a brief tabulation of some prices paid recently for large ferries in Canada and overseas, it appears that the premium for Canadian construction might be of the order of 50% to 100% of the off-shore price.[53] Some corroboration is provided by comparisons of costs for other types of vessels; for example, a price for construction in Canada of a seaway-size bulk freighter is double that of one built in Korea.[54] To the off-shore prices must be added 25% duty, but the differential remains substantial.

For illustrative purposes, it is assumed that the premium for local construction amounts to 33% of the capital cost of the vessel. This proportion is therefore deducted from the vessel capital costs included in the accounts for Marine Atlantic and BC Ferries. The vessel costs are not separately identified for Northumberland Ferries, so no such deduction is made; but the effect of this omission on the system average costs is negligible.

The resulting costs per passenger-vehicle-kilometre, amended for both food services (cost and revenue) and local vessel construction premiums, are:

| | Costs | Revenues |
|---|---|---|
| | ($/passenger-vehicle-kilometre) | |
| BC Ferries | 0.73 | 0.62 |
| Marine Atlantic | 1.74 | 0.71 |
| Northumberland Ferries | 2.28 | 1.01 |

### 8.5.3 Estimation of Costs per Passenger-Kilometre

The earlier cost and revenue estimates attempted to exclude all elements relating to freight transportation. In estimating the costs per ferry passenger-kilometre for comparison with the other modes, it is necessary to distinguish the passengers on ferries who travel in passenger vehicles from the occupants of freight vehicles, who are also described as passengers in the ferry statistics. Assuming 1.1 occupants per commercial vehicle, there were 637,000 passengers in commercial vehicles, or 2.8% of the total of some 22.8 million passengers in 1990-91, for the three companies. Because the commercial vehicle passengers are so small a proportion of total passengers, the subsequent estimate of total passenger-kilometres is clearly not very sensitive to the guessed number of occupants per commercial vehicle.

For BC Ferries and Marine Atlantic, this procedure for estimating "non-commercial passenger-kilometres" was applied to each of the services, allowing overall estimates of 640 million passenger-kilometres for BC Ferries and 135 million passenger-kilometres for Marine Atlantic. For Northumberland Ferries, the amended estimate is 12.07 million passenger-kilometres. Expressed alternatively as numbers of passengers per passenger-vehicle carried by the three companies, the results are as shown in the second column of Table 3(2)-11. The cost and revenue estimates in the previous tables can be divided by these estimates of passengers per vehicle to give costs and revenues per "non-commercial passenger-kilometre" in the final two columns of Table 3(2)-11.

*Table 3(2)-11*
*AVERAGE FERRY UNIT COSTS AND REVENUES*

| | Passengers per passenger-vehicle | Costs ($ pass-km) | Revenues ($ pass-km) |
|---|---|---|---|
| BC Ferries | 2.59 | 0.282 | 0.239 |
| Marine Atlantic | 2.43 | 0.718 | 0.292 |
| Northumberland Ferries | 2.48 | 0.921 | 0.408 |
| Average | | 0.366 | 0.250 |

The system-average vehicle/carrier cost estimate for ferries is therefore 36.6¢/pass-km, and the "user-borne" portion is 25¢/pass-km.

In the illustrative tables of Volume 1, Chapters 3 and 18, amounts borne by vehicle users/carriers and passengers for accident costs and special transportation taxes/fees are shown separately. In the case of ferries, all of these costs are included in the estimated averages of 36.6¢/pass-km and 25¢/pass-km; thus, they must be deducted to show the remaining vehicle/carrier costs.

### 8.5.4 Estimation of Special Tax/Fee for Ferry

As the first step in the calculation of special taxes, the amount of fuel used in the ferry services must be estimated per passenger-kilometre. Marine Atlantic provided data for the company's fuel purchases and expenditures over a three-year period.[55] Direct estimates of fuel used by BC Ferries and Northumberland Ferries were not available; estimates based on their expenditures on fuel[56] in 1990, together with an assumed average price of 26.5¢/L plus provincial tax, were used. These estimates suggest a combined total fuel consumption of about 195 million litres for the three ferry companies.

These estimates of consumption were then allocated between freight and passenger vehicles for each company in the same manner as were costs; that is, according to proportions of auto-equivalent units transported. Then the estimates of total (non-commercial) passenger-kilometres for the three companies were used to calculate litres of fuel consumed per passenger-kilometre. The resulting estimate is 0.191 L/pass-km.

The average special tax payable per litre for these ferry services was then calculated. This involved a calculation analogous to that for the special tax component of prices of gasoline used in cars, as discussed earlier. Federal excise and provincial fuel taxes paid, by province, in 1991, on marine fuels are shown in Table 3(2)-12. The amount of provincial tax that would have been payable had the normal sales tax rate been applied to the price of marine fuel was then calculated — also shown in Table 3(2)-12. Finally those amounts were deducted from the total of the federal excise and provincial taxes paid to obtain the net amounts of special transportation tax paid.

*Table 3(2)-12*
*SPECIAL TAX CALCULATION: FERRY*
*(TAXES IN 1991¢/L OF MARINE FUEL)*

| | Nfld. | P.E.I. | N.S. | N.B. | B.C. |
|---|---|---|---|---|---|
| Federal excise | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 |
| Provincial tax | 0.0 | 0.0 | 1.2 | 0.0 | 3.34 |
| Tax at PST rate | 3.9 | 3.3 | 3.3 | 3.6 | 1.5 |
| Net special tax | 0.1 | 0.7 | 1.9 | 0.4 | 5.8 |

To estimate the amounts of fuel used in the east-coast services bought in each province, it is simply assumed that half the fuel used in each of the ferry services is purchased at each end of the trip. The weighted average tax rate paid on the Marine Atlantic services would then be 0.96¢/L, on Northumberland Ferries' services 0.55¢/L, and on the BC Ferries' services, as shown in Table 3(2)-12, 5.8¢/L.

Then, by multiplying these taxes by the estimated consumption per passenger-kilometre, the average special fuel tax payment for all the ferry services is estimated as 0.87¢/pass-km. This is included in the system-wide costs in Table 3.1, appearing as 0.9¢/pass-km when rounded.

The amount of this tax must be deducted from the vehicle/carrier costs together with ferry accident costs, estimated at 0.075¢/pass-km. Resulting user-borne vehicle/carrier costs are reduced from the 25¢/pass-km estimated earlier, to 24.1¢/pass-km, while total vehicle/carrier costs are reduced from 36.6¢/pass-km to 35.7¢/pass-km.

## 9. COSTS FOR SAMPLE ROUTES

### 9.1 CAR

For simplicity, in these illustrations most of the costs of car use are assumed to be constant per kilometre, regardless of route. In reality, vehicle fuel consumption would differ among the routes, being determined by such factors as travel speed and the extent of congestion. Vehicle maintenance and depreciation per kilometre would also vary by those factors, and be influenced by the quality of the highway pavement. Accident risks and, therefore, expected accident costs, are also known to vary by route and traffic conditions. Nevertheless, it is assumed here that such variations are not important to the major purpose of these estimates, which is to show the orders of difference in costs by mode, and subsequently (in Chapter 18) to show the future cost changes expected. Each of these classes of costs is therefore assumed to be the same per vehicle-kilometre on all of the sample routes as the system-wide averages estimated earlier. Also for simplicity, and in the absence of much information, average vehicle occupancies are assumed constant for all sample routes, so these categories of costs remain the same per passenger-kilometre as the system-wide averages.

The exceptions are the highway infrastructure costs and the environmental costs, which are assumed to vary by route, as described in subsections 9.1.1 and 9.1.2.

### 9.1.1 Costs of Infrastructure

The estimates of highway construction and maintenance costs prepared by Nix et al. and shown in Table 3(2)-3, earlier, differ substantially by class of highway. Adding the cost of capital to those estimates, and inflating to 1991 prices, produces the costs per vehicle-kilometre, which appear in the second column of Table 3(2)-13(i). The proportions in which each class of highway are represented differ among the sample routes, so the average infrastructure cost should also differ by route. The proportions have been estimated only roughly by Royal Commission staff. The estimates made for the four sample routes in Volume 1, Chapter 3 and also for the additional routes in Chapter 18, are as shown in part (i) of Table 3(2)-13.

Part (ii) of Table 3(2)-13 then shows the resulting estimates of costs averaged over the highway types for each of the routes, expressed as costs per vehicle-kilometre and per passenger-kilometre. It can be seen that they differ substantially, being lowest for the all-expressway route between Toronto and Montreal and greatest for the predominantly low-density rural highway route between Winnipeg and Gillam.

The estimates of car infrastructure costs for the sample routes are produced by adding the system-average cost of infrastructure control per passenger-kilometre from subsection 5.1.4., of 0.22¢/pass-km, to the costs per passenger-kilometre in Table 3(2)-13. In addition, for the route from Toronto to Montreal an estimate of the highway land cost of 0.3¢/pass-km, or $1.60 per passenger-trip, is included. Land costs are ignored on the other routes, as they are expected to be much less important within the trip totals.

Table 3(2)-13

## HIGHWAY CONSTRUCTION AND MAINTENANCE COSTS FOR SAMPLE ROUTES, INCLUDING COST OF CAPITAL, IN 1991 PRICES

| (i) Costs per vehicle-km, and route distance by class of highway | | | | | | | | | |

### 9.1.2 Environmental Costs

As well as differing because of trip lengths, costs of environmental damage are expected to differ among the illustrative routes because of the different distances travelled within the ozone non-attainment areas (ONAs). In fact, because fuel consumption, and implicitly other engine operating conditions, are assumed constant among the routes, emissions are also constant per vehicle-kilometre. The cost for $CO_2$ (at 3.27¢/kg, as described in the Notes to Chapter 7 in this volume) is therefore also constant per vehicle-kilometre for all routes, at about 0.73¢, or 0.41¢/pass-km.

The cost of emissions of $NO_x$ and VOCs, however, is assumed to be $5/kg only within the ONAs, and only during summer. Otherwise the cost is zero. The portion of each of the sample routes assumed to lie within the ONAs is shown in Table 3(2)-14, for the other modes as well as for car travel. Emissions per vehicle-kilometre are assumed constant during each trip; therefore, the proportion of trip-kilometres within the ONAs represents the proportion of trip emissions within those areas. The fraction of emissions that occur in summer is assumed to be constant at 40%. That portion of the total $NO_x$ and VOCs emissions on each route in ONAs in summer is multiplied by $5/kg to obtain the cost for each route.

A more comprehensive explanation of the derivation of the costs on two of the sample routes, Toronto to Montreal and Saskatoon to Halifax, forms part of the Notes to Chapter 7 in this volume.

## 9.2 BUS

### 9.2.1 Costs of Infrastructure

The costs for highway construction and maintenance per bus-kilometre estimated by Nix et al., in Table 3(2)-3, also differ substantially by class of highway, and therefore vary among the sample routes as the types of highways represented differ. Distances by class of highway are assumed to be as described for cars, shown in Table 3(2)-13(i).

Table 3(2)-14

### TRIP DISTANCES BY MODE, AND DISTANCES IN OZONE NON-ATTAINMENT AREAS FOR SAMPLE ROUTES

| | Toronto-Montreal | | Saskatoon-Halifax | | Val d'Or-Montreal | | Vancouver-Toronto | | Winnipeg-Churchill | | Halifax-St. John's | | | |

| Ferry | — | — | — | — | — | — | — | — | — | — | 178 | 0 | 519 | 0 |

Source: Royal Commission staff estimates.

a. Airplane kilometres in "ozone-sensitive areas" assumed to be 50 km per trip-end within such areas.

The second column shows the costs per vehicle-kilometre for buses by class of highway.

Part (ii) of the same table shows the weighted average cost per bus-kilometre over each route. As for cars, the lowest cost per vehicle-kilometre is incurred over the expressway route between Toronto and Montreal, and the highest over the low-density rural highway route between Winnipeg and Gillam.

The table then shows, in the next-to-last row, the Royal Commission staff estimates of average bus occupancies over routes of these types, and the last row shows the average cost per passenger-kilometre by route, obtained by dividing the cost per vehicle-kilometre by the occupancy on each route.

### 9.2.2 Environmental Costs

Emissions of $CO_2$, $NO_x$ and VOCs from buses are assumed to be constant per litre of fuel used, as described in the Notes to Chapter 7 in this volume. They therefore vary per vehicle-kilometre by route only to the extent that fuel use per vehicle-kilometre varies, and also vary per passenger-kilometre to the extent that bus occupancies differ.

Fuel use per bus-kilometre is estimated by Royal Commission staff to be constant at 40 L/100 bus-km on most of the sample routes. Occupancies are assumed to vary by route as was shown in Table 3(2)-13(ii). The resulting fuel use per passenger trip for buses is shown in Table 3(2)-15, which also includes fuel use in the other modes. Emissions by route are obtained by converting the fuel use into $CO_2$, $NO_x$ and VOCs emissions by the factors implicit in Table 7(2)-1 and 7(2)-2, which appear later in this volume.

Then costs of the emissions by route are calculated as described above for cars. Total trip emissions of $CO_2$ are multiplied by the assumed cost of 3.27¢/kg. Emissions of NOx and VOCs are first multiplied by the portion of trip-kilometres in the ONAs, also shown in Table 3(2)-15, and by 40% to represent summer; then remaining emissions are multiplied by $5/kg.

*Table 3(2)-15*

### FUEL USE PER PASSENGER-TRIP BY MODE ON SAMPLE ROUTES

**Source:** Royal Commission staff estimates.

[a] Airplane fuel use in takeoff/landing assumed to be 35 litres per passenger.

## 9.3 TRAIN

### 9.3.1 Costs of Infrastructure

The infrastructure costs, as for the carrier costs, are taken from data provided by VIA Rail and Transport Canada. Infrastructure costs are presumed to be payments to the freight railways for the service in question.

### 9.3.2 Environmental Costs

Emissions are assumed to be constant per unit of diesel fuel energy, as shown in Table 7(2)-1 in this volume. Estimated diesel-fuel use per passenger-trip for each sample route is shown in Table 3(2)-15. The two are combined to give emissions of $CO_2$, $NO_x$ and VOCs per passenger-trip. Total $CO_2$ emissions are multiplied by a cost of 3.27¢/g. Costs of $NO_x$ and VOCs are calculated by applying the unit cost of $5/kg to the portion of emissions released in the ONAs (from the trip-kilometres in ONAs in Table 3(2)-15) in summer (40%).

## 9.4 AIRPLANE

### 9.4.1 Costs of Infrastructure

The allocation of air infrastructure costs to individual sample routes is illustrated in subsection 5.3.3 of this Chapter.

### 9.4.2 Environmental Costs

Emissions are again assumed to be constant per unit of fuel energy among the sample routes, at rates shown in Table 7(2)-1 of this volume. Estimates of fuel use per passenger-trip are provided in Table 3(2)-15. The two are combined to give emissions of $CO_2$, $NO_x$ and VOCs per passenger-trip.

Total $CO_2$ emissions are multiplied by a cost of 3.27¢/g. Amounts of $NO_x$ and VOCs occurring in the ONAs are calculated somewhat differently for aircraft than for the other modes. Instead of using the proportion of route-kilometres that lies within the ONAs, it is assumed that the aircraft fuel used on the ground, climbing and descending at airports within the ONAs contributes to low-level ozone, while fuel used at cruising altitude does not. The relevant amount of fuel (for aircraft of a Level 1 carrier) is estimated by Royal Commission staff to be about 35 litres per passenger-stage. The proportion this represents of fuel used per passenger-trip by route is shown in Table 3(2)-15. This proportion of trip emissions, multiplied by 40% to represent summer, is multiplied by $5/kg to obtain the $NO_x$/VOCs cost per passenger-trip.

## 9.5 FERRY

No route-specific ferry costs are shown in Chapter 3, but 1991 costs for ferry routes are included in Chapter 18. The examples in Chapter 18 are of the two ferry routes between Nova Scotia and Newfoundland. Costs per passenger-kilometre for infrastructure and accidents are assumed to be the same as the system average.

### 9.5.1 Vehicle/Carrier Costs

Costs for the two routes are obtained from the research report that provided the system-average costs.[57] The same procedures described earlier for the system-average costs were used to remove costs of food services and excess vessel costs arising from local construction, and to estimate fuel costs and taxes in order to distinguish the special tax/fee for the routes.

### 9.5.2 Environmental Costs

Emissions are again assumed to be constant per unit of fuel energy, as shown in Table 7(2)-1. Fuel use on the two illustrative ferry routes is assumed to be the same per ferry-kilometre, and per passenger-kilometre, and therefore differs per passenger-trip only by route length, as shown in Table 3(2)-15. No costs for $NO_x$ and VOCs are assessed on either of these routes, as their emissions are assumed to occur entirely outside the ONAs.

# ENDNOTES

1. Cross subsidy, in this context, implies that the hypothetical service in question makes more than the average contribution to fixed cost. Most economists would not use this (implied) definition of cross subsidy.

2. Estimates developed from Statistics Canada, *Passenger Bus and Urban Transit Statistics*, Catalogue No. 53-215, 1989; bus fuel consumption data; bus company accounts; and assumed load factors.

3. Treasury Board of Canada, *Benefit-Cost Analysis Guide* (Ottawa: Supply and Services Canada, 1976).

4. There are two methods of accounting for capital costs: investment expenditures can be included in total costs in the year in which they are made, or they can be amortized over time in such a way that the stream of annual "depreciation charges" and of annual "interest charges" (or return on capital) has the same discounted present value as the initial investment expenditure. The latter approach gives a smoother stream of annual costs and provides a better estimate of the cost of using the facility in a particular year. The Royal Commission's cost analysis work uses this amortized cost approach; a real rate of return of 10 percent, applied to one-half the replacement value of the facility, is used to estimate the "interest charge."

5. F. P. Nix, M. Boucher and B. Hutchinson, "Road Costs," in Volume 4 of this report.

6. Ashish Lall, "Transportation Infrastructure Costs in Canada," in Volume 4 of this report.

7. Z. Haritos, *Rational Road Pricing Policies in Canada* (Ottawa: Canadian Transport Commission, 1975), and Strategic Policy Directorate, Transport Canada, *Transport Costs and Revenues in Canada* (Ottawa: Transport Canada, July 1982).

8. The term "expressway" is used to denote a limited access highway.

9. An alternative means of estimating the capital value of the highway stock would be creating average lifetime profiles of costs of construction and repair per kilometre for highways of various qualities, and combining them with estimates of the age profiles of various parts of the network. The necessary unit costs — particularly of costs of new construction of highways of various qualities — and age profiles are not available. Some possible indication of the relevant amounts can be obtained using costs of reconstruction from the report by Nix et al., "Road Costs," to represent costs of new construction (which understates construction costs by the amounts needed for preparation, grading, drainage, etc.). By adding resurfacing and reconstruction costs as also indicated by that report, lifetime profiles of costs by type of highway can be created. Then, assuming highways are of average age (that is, that construction was spread evenly over the last 45 years or so), the following current capital values can be estimated:

| | | $ million (at 1989 prices) |
|---|---|---|
| Expressways | | 1,860 |
| Paved rural highways | top 10% | 1,630 |
| | middle 30% | 4,160 |
| | bottom 60% | 7,920 |
| Total | | 15,600 |

A capital charge at 10% on that total would amount to $1.56 billion per annum. When allocated by vehicle type by passenger car equivalent units, this charge per passenger kilometre for an average car/light truck would amount to approximately 0.5¢/pass-km.

This method would produce the same cost as does the guesswork in the text — that is, close to 1¢/pass-km — if the true unit costs of new construction (per kilometre) were about double those drawn from Nix et al. for reconstruction. It seems quite probable that new construction costs are that much higher.

12. Deliberately ignoring the tolls on international bridges, recognizing that the costs of those bridges do not appear in provincial/federal roads budgets, and are therefore not included in our costs.

13. British Columbia Ministry of Transportation and Highways, *Annual Reports*, 1988–89 and 1989–90.

14. Personal communication, British Columbia Ministry of Transportation and Highways.

15. Maximum gross weight quoted for "B-train double," with exceptions being in Ontario and Yukon, where the limit is 63.5 tonnes. See Council of Ministers of Transportation and Highway Safety, Interjurisdictional Committee on Vehicle Weights and Dimensions, *Summary of Weight and Dimension Regulations for Interprovincial Operations, Resulting from the Memorandum of Understanding on Interprovincial Weights and Dimensions*, September 1989 (available from Canadian Council of Motor Transport Administrators, Ottawa).

16. Nix et al., "Road Costs."

17. Ibid., from Table E.6, average obtained from weighting by vehicle-kilometres by class of highway, and inflating from 1989 to 1991 prices at 4.5% per year.

18. The equivalent standard axle load of a candidate vehicle or axle is defined as the number of passes of a "standard axle load," of 18,000 lb. (8 163 kilograms) on a single axle supported by four tires, required to create the same amount of damage as one pass of the candidate axle load. In customary form ESALs have been calculated from the "fourth-power law" of pavement damage. See Nix et al., "Road Costs," subsection 2.3.3.

19. See subsection 5.1.2. for the derivation of capital costs for cars. Allocating 40% to 60% of the total highway capital stock of $59 billion to highways, and 25% (by PCE-kilometres) to heavy trucks, applying an annual capital charge of 10%, and averaging over 16 billion vehicle-kilometres gives 3.7¢ to 5.5¢/veh-km.

20. F.P. Nix, *Road-User Costs*, Report TP 9766 (Ottawa: Transport Canada, April 1989).

21. As noted in the report by Nix et al., "Road Costs," use of the cost formula with "Waterloo Load Equivalency Factors" instead of ESALs would raise the estimated cost per vehicle-kilometre by some 40% to 50%.

22. It should be noted that the estimates of what are referred to as "marginal pavement costs" in the report by Nix et al. are not directly comparable, either in units of measurement or in concept, with the conventional definition of marginal cost of pavement wear. The latter refers to the cost of wear associated with passage over the pavement of one truck. The report investigated the way in which capital construction costs plus the present discounted value of resurfacing costs over the life of the highway vary with traffic volume, including volume of heavy truck traffic, assuming road and pavement structure are optimal given the traffic volumes. Thus, the report's "marginal pavement cost" represents the estimated increase in discounted life-cycle investment expenditures (a capital stock concept not an annual cost) as the average annual traffic volume increases. Further, the report does not directly address the issue of estimating truck wear on existing highways that may not be optimally matched to traffic volume.

23. Sypher : Mueller International Inc., *Air Infrastructure Costing*, a report prepared for the Royal Commission on National Passenger Transportation, RR-04, August 1991.

24. For the eight largest sites (Dorval and Mirabel are considered as one) or major federal airports (MFAs), which were part of the now discontinued Airports Revolving Fund, financial statements are produced on an annual basis, which conforms to generally accepted accounting principles. The statements are contained in a publicly available document produced each year by Transport Canada entitled "TP 1300 Airports Revolving Fund, Financial Statements for the year ended 19_ _".

    For the next 14 largest sites, which were once part of the Airport Revolving Fund and are now known as federally dependant airports (FDAs), annual financial statements are produced by the site financial officers and submitted to the Financial Advisor of the Airports Group at headquarters. Although these statements are not published or audited like the MFA sites, copies can be obtained through headquarters personnel and represent a reasonably accurate source of site costs and infrastructure.

    For the remaining sites, which are also classified as FDAs, financial statements are not prepared on an annual basis and are only available on a timely basis when Transport Canada undertakes special studies to update the Department's historical financial data base. A complete update of this data base was last undertaken for the fiscal year 1987-88.

25. Costs have been allocated to three user groups — commercial, instrument flight rules (IFR) general aviation (ga), and visual flight rules (VFR) ga. Commercial includes unit toll, charter, and other commercial operations. Unit toll is defined as the transport of people or goods on a toll or price per person or unit. Charter is the transport of a person or good for a price to hire the aircraft per kilometre or hour. Other commercial operations include flights performed by commercial aircraft other than the unit toll or charter services. IFR ga includes itinerant movements of operators using radio navigation instruments to assist the pilot. VFR ga includes itinerant and all local movements of operators not using radio navigation instruments. In general terms, IFR ga tends to use larger, more sophisticated aircraft, while VFR ga tends to use smaller aircraft.

26. See D. Gillen and T. H. Oum, "Transportation Infrastructure Policy: Pricing, Investment and Cost Recovery," in Volume 3 of this report.

27. No readily accessible source of data was available for the replacement cost of Transport Canada's fixed assets; however, historical book value and accumulated depreciation were available on a site-specific basis.

    To develop a reasonable proxy for capital charges based on replacement value for each site the accumulated depreciation was divided by the average annual depreciation expense to estimate the average life of the asset base. From this, an average original year of expenditure for the base was calculated. This original year was then used to determine the cost-escalation factor based on the Statistics Canada's Implicit Price Index for Total Construction, which was applied to the original book value to restate it in terms of 1990–91 dollars. If the asset base increased by more than 20% in any one year, the amount of the expenditure was removed from the cost base and inflated by the factor that corresponded to the year of the expenditure.

28. Transport Canada, *1989–90 Estimates: Part III, Expenditure Plan* (Ottawa: Supply and Services Canada, 1989).

29. On a movement allocation basis, this would be: 4 movements at $42.54 + 3 500 kilometres at $0.15 = $695. Divided among a typical 85 passengers, this amounts to $8 per passenger.

31. Statistics Canada, *Rail in Canada, 1989*, Catalogue No. 52-216, 1991.

32. Transport Canada, *Proposed New Cost Recovery Policy: Phase II Discussion Paper*, Report TP 10041 (Ottawa: April 1990), Table 14, updated with values for fiscal year 1990–91 by personal communication from Economic Evaluation and Cost Recovery Directorate, Transport Canada.

33. Most of the estimates of the willingness-to-pay for risk reductions are expressed as values per death avoided, when the risk reductions involve reductions in both deaths and injuries. It is not then appropriate to add to the material losses from injuries a further value for willingness-to-pay to avoid emotional losses through injury. The value of the material losses is therefore used for injured victims, $10,000 per victim.

34. Only in a minority of accident cases is there a court determination of compensation. Other cases settled out of court might include compensation for emotional losses, and in a larger number there is some nominal payment based on the insurance contract. Compensation in all such cases is unlikely to be as great as the cost inferred from the willingness of users to pay for risk reductions.

41. For the purpose of this analysis, an airplane (or seat or passenger) stage is defined as a take off and a landing. A flight may involve additional takeoffs and landings (intermediate stops) but with a single flight coupon and not normally a change of airplane. A trip may include multiple flights but is not broken for purposes other than onward connections.

42. Statistics Canada Catalogue No, 51-005, 51-204 and 51-206 for 1988, 1989 and 1990; Air Canada and PWA Corporation Annual Reports for 1988, 1989, 1990 and 1991 (PWA only).

43. This is a more restrictive definition than that used to estimate the cost of an average domestic trip later in this section. Any change of airline, even to an affiliated carrier, or from domestic to international flights, is counted as an additional passenger trip in the Statistics Canada data, which was partially used to develop this model.

44. As these data were quite uncertain, given the variety of sources, a variant of the model to test the sensitivity of the unit cost estimates to these parameters — particularly the number of flights in the average trip — was run. An assumption of 1.35 flights per trip — more than doubling the assumed proportion of multi-flight trips — resulted in increases in estimated vehicle/carrier cost for the sample routes that ranged from 2.5% for Saskatoon–Halifax to 6.5% for Toronto-Montreal. In the context of the Royal Commission's analyses, this is not significant.

45. The pass-km and stage-km elements of the cost would be more accurately computed using the actual load factors for the stages involved, if these were known. For the present purpose — portrayal of typical cost — the system average Level 1 figure is more appropriate.

46. Inflated from data presented in S. A. Morrison, "Deregulation and Competition in the Canadian Airline Industry," in Volume 4 of this report.

47. As was shown in Table 3(2)-8, combined federal and provincial aviation turbo fuel taxes net of provincial sales tax vary from 0.6¢/L in Newfoundland and 1.3¢/L in Nova Scotia to 9.1¢/L in Saskatchewan. A system-average special tax/fee rate of 5.8¢/L was calculated as a weighted average of consumption of aviation turbo throughout the country. Inasmuch as the system average is calculated for all aviation consumption, it may not be entirely accurate for domestic, as opposed to international, services. A greater source of uncertainty applies to the route-specific estimates. These are based on the assumption that the quantity of fuel consumed during each stage travelled is taxed in the jurisdiction where that stage commences. In the case of Halifax–St John's, the assumed special tax/fee shown is therefore very low, and the tax for a seat-stage taking off from Saskatoon has been assumed to be high. Of course, aircraft do not always take on fuel before every takeoff, or in the exact quantity to be consumed during the succeeding stage. Subject to overriding safety considerations, airlines manage their fuel acquisition to minimize their costs of operation, of which fuel cost — including taxes — is an important element.

# ANNEX 1: OPPORTUNITY COST OF HIGHWAY LAND

An attempt is made here to estimate the amount of land occupied by the highway network, and its opportunity cost, in terms of value in reasonable alternative use.

## ROUTE-KILOMETRES BY PROVINCE

The lengths of highways are obtained from the annual statistical publication of the Transportation Association of Canada.[1] The estimated route-lengths by province are shown in Table 3(2)-A1, and total 8 220 km of expressway and 129 016 km of paved rural highway.

## AREA OF LAND DEDICATED TO HIGHWAYS

The width of land used for expressways varies substantially depending on the nature of the terrain and surrounding land use, as well as the number of lanes, widths of medians, shoulders, and so on. It is assumed for simplicity that the average width of the right-of-way for conventional four-lane rural expressways is 100 m. This is believed generous — leading again to a possible slight over-estimate of land use. For two-lane rural highways, the standard width of right-of-way is 100 feet (30.5 m).

A simple calculation then allows an estimate of the total area of land taken by expressways as 82 000 hectares, and of that occupied by rural highways as 393 000 hectares, for a total of 475 000 hectares. Provincial estimates are also shown in Table 3(2)-A1.

---

[1] In recent years, for example, Transportation Association of Canada, *Highways in Canada: 1991 Report*, (Ottawa: TAC, 1991), these figures have been presented only in "equivalent two-lane kilometres," but estimates of the route-kilometres are possible by reference to the publication for 1985, Roads and Transportation Association of Canada, *Roadway Infrastructure Study* (Ottawa: RTAC, 1987). For "paved rural roads" it is reasonable to assume that two-lane kilometres are identical to route-kilometre, as the 1985 publication showed the former to be less than 2% greater than the latter (and this assumption will therefore produce a very slight over-estimate of land costs). For expressways, the adjustment is more important, as the difference between two-lane kilometre and route-kilometre is shown by the 1985 publication to be large, and to differ substantially by province. The particular assumption made here is that the average freeway is four lanes, with the exceptions of Quebec and Nova Scotia, for which the 1985 publication showed that the expressways had fewer lanes than the national average. It has been assumed for both provinces that the 1985 highways still exist, and that all expressway-kilometres added since that date have been of four-lane standard.

*Table 3(2)-A1*

### AREA AND VALUE OF LAND USED FOR PROVINCIAL EXPRESSWAYS AND HIGHWAYS, 1990

| | B.C. | Alta. | Sask. | Man. | Ont. | Que. | N.B. | N.S. | P.E.I. | Nfld. | All provinces |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Expressways: | | | | | | | | | | | |
| – route-km | 427 | 1,232 | 24 | 0 | 1,882 | 3,200 | 110 | 1,300 | 0 | 45 | 8,220 |
| – rural hectares | 4,227 | 12,197 | 238 | 0 | 18,632 | 31,680 | 1,089 | 12,870 | 0 | 446 | 81,378 |

**Urban residential land values derived by Royal Commission staff from house prices provided by Canada Mortgage and Housing Corporation.**

## OPPORTUNITY COST OF THE LAND

In attempting to identify this opportunity cost, it is tempting to look at the market prices commanded by equivalent land close by. But this is subject to a conceptual criticism: surrounding land use can be substantially altered by the existence of the highway. In general, the accessibility provided by the highway generates more surrounding activity than otherwise, and raises the market value of the surrounding land.

For the rural land used for highways in Canada, this concern is probably not of practical importance. One can probably simply look to the use of the land prior to the highway being built, or consider what the use would revert to if the highway were scrapped, and come to a similar conclusion about the realistic opportunity costs. If there were only local access (through the grid road system), the land would probably be usable only for some form of agriculture or forestry, or might not be suitable for either and remain unused. No information is available to estimate which portions of Canadian highways would revert to each of these purposes, nor are details available of actual land prices by location, from which it might be possible to estimate values of land used for specific highways. The average prices of farmland by province, however, are available, and are shown in Table 3(2)-A1.[2] Such averages are province-wide, and might represent land on average that is even more remote from settlements than the land used for highways. On the other hand, these prices are for the portions of land that are usable for farming, when much of the land on which highways are constructed would likely otherwise be too poor for farming, and worth even less. These prices for farmland can be used as an indication of the alternative value of land used for highways, in the expectation that they probably overestimate the true opportunity costs.

The complexity is greater for urban land occupied by highways. Accessibility increases the value of the adjacent land. Therefore the opportunity cost of the highway land should not be represented by the market value of adjacent land, but more reasonably by that of equivalent land that does not have the accessibility advantage from the highway. It could be difficult, if not impossible, to identify such "equivalent land," without some other accessibility advantage. Again, the logical test might be the value that the land could command if the highway were entirely abandoned. It seems reasonable to assume that the land would otherwise be served simply by local access streets, and be usable for residential or commercial purposes comparable with land similarly served in the community concerned.

---

[2] Personal communication from Agriculture Division, Statistics Canada, February 1992.

For illustrative purposes, it is assumed that the alternative use would be for residential purposes, with value equal to the average price of land for new house construction for the entire cities concerned (therefore reflecting the total accessibility advantages gained from the communities' transport connections, but with no premium from direct proximity to any particular connection).

Estimates of average new detached/semi-detached house prices in 1991 were obtained from Canada Mortgage and Housing Corporation (CMHC).[3] The appropriate national average of residential land prices is elusive, as CMHC does not provide estimates of new house prices for all of the communities on the national network. Instead, one can only guess at the relevant price from the averages for those larger communities that are provided. These show that the average new house price in 1991 among the 25 largest metropolitan areas was $197,000, of which approximately 30% is the land component, or about $59,000. Among the 52 largest communities, the value was $149,000, and the land component[4] at 30% amounted to approximately $50,000. These communities feature prominently in the primary highway network, but so do a much larger number of smaller communities.

---

[3] In personal communications between Royal Commission staff and staff from Statistics Division of CMHC, Feb. 27,1992.

[4] Information provided by Statistics Canada and CMHC by city suggests that the land proportion of the total house price is surprisingly constant at nearly 30%, when total prices ranged between $109,000 and $305,000 among the cities covered. As the information is compiled from reports made by builders, it is possible that they are using a simple rule-of-thumb of 30% in their responses.

Furthermore, those land values are for serviced land and for detached houses. The average value for urban land occupied by highways is probably therefore substantially lower. For illustration, an average value is assumed of $30,000 for a lot of 4,000 square feet (370 $m^2$). With five lots per acre (or, more than 12 per hectare), allowing for services, this suggests values of unserviced land of about $150,000 per acre, or $371,000 per hectare, in 1990 prices.

The area of urban land involved is not large as a proportion of total land used for highways, but, as will become obvious in the examples that follow, the precise amount and its value is crucial to the estimate of the total value of the land used. No record is available of the length of the urban portions of the highway system; that is, those portions that, in the costing scheme, are assumed to displace residential land rather than farmland. It seems certain that the proportion cannot be as much as 5% (1 km in 20, or 7 000 km of the entire 140 000 km of primary highways being in urban areas), and more likely is closer to 1% (1 km in 100, or 1 400 km in total). A proportion of 1% of the highway system will represent urban portions.

## RESULTS OF ALTERNATIVE ESTIMATES

### Alternative Value as Farmland

Table 3(2)-A1 shows the value that the road network would have if the only alternative use of the entire system was as farmland. Using the average farmland prices provided by Statistics Canada, the 82 200 hectares of expressways would be worth $111 million, and the 393 000 hectares of 2-lane highway would be worth $470 million, giving a total for the whole system of $581 million.

### Alternative Rural Value as Farmland, Urban Value for Housing

Table 3(2)-A1 also shows estimates for the opportunity costs of the land if 99% of it is rural, usable for farming, and the other 1% is in urban areas, usable for residential development. The essential assumptions from above are:

| | |
|---|---|
| • Expressway right-of-way width | 100 metres |
| • Paved 2-lane highway right-of-way width | 100 feet |
| • Proportion of all highways in urban areas | 1% |
| • Average price of urban residential land per unserviced hectare | $370,000 |

The urban portions of the highway network have an estimated value of $1.8 billion. The total value of the urban and rural systems is now estimated at $2.4 billion. The importance of the assumptions about the area and value of the urban portions can be appreciated, as the rural part of the network, while 99% of the total length of the system, has an alternative value at farmland prices of $570 million, only 24% of the total value.

It is judged that this latter estimate, including urban land valued by its potential alternative development, is more appropriate than valuing the entire land as farmland. The estimate is therefore converted to a cost per passenger-kilometre, as follows.

### Estimated Opportunity Cost of Land per Passenger-Kilometre

In order to compute these land costs per unit of traffic, the capital value of the land is converted into an annual sum, using a real rate of 10% per year as the opportunity cost rate.

Land costs are then allocated between private passenger and other vehicles according to the number of "passenger-car-equivalent-kilometres" they contribute annually. As noted earlier, this procedure allocates some 70% of costs to cars/light trucks in passenger use.

Also as noted earlier, annual traffic on the highway network by cars and light trucks in passenger use is estimated as 120 billion vehicle-kilometres, and 210 billion passenger-kilometres.

The results of the computations are as follows:

| | |
|---|---|
| Total capital cost of land | $2,400 million |
| Annualized cost at 10% | $240 million per year |
| Annualized cost attributable to cars | $170 million per year |
| Cost per passenger-kilometre | $0.0008 |

In conclusion, using the base-case assumptions, the total land value is estimated as approximately $2.4 billion, which, when annualized at real interest rate of 10% in perpetuity produces a value of approximately 0.08¢/pass-km. Given the uncertainty in this estimate, it is incorporated in the highway infrastructure cost estimates, rounded to 0.1¢/pass-km.

# ANNEX 2: OPPORTUNITY COST OF AIRPORT LAND

The dimensions of the nine major federal airports, together with the latest appraisals (by purpose) of the land available at each of the sites, were made available by Transport Canada,[1] and are shown in Table 3(2)-A2. The appraised values are for actual parcels of land on the airport property available for the specified uses. Objective appraisers (usually Public Works Canada) rate the property based on its characteristics and comparisons with land used for similar purposes in the immediate area.

*Table 3(2)-A2*

*APPRAISED VALUE OF LAND AT MAJOR FEDERAL AIRPORTS, 1991, BY PURPOSE*

| | Size | Value appraised per square metre, by type of use | | | | | |
|---|---|---|---|---|---|---|---|
| | (hectares) | Light industrial with air-side access ($) | Light industrial ($) | Commercial ($) | Heavy industrial with air-side access ($) | Heavy industrial ($) | Agricultural ($ per hectare) |
| Halifax | 951 | 30 | — | 36 | — | 17 | (870)[a] |
| Mirabel | 6,920 | 28-35 | 23–28 | 32–82 | 12–24 | 10–20 | 1,400 |
| Dorval | 1,668 | 75 | 45 | 100 | — | 25 | — |
| Pearson | 1,715 | — | 68–79 | 124 | — | 50 | — |
| Ottawa | 2,086 | — | 78–90 | 100–120 | — | 40 | — |
| Winnipeg | 1,504 | 35 | — | 40 | — | 30 | — |
| Edmonton | 2,800 | 21 | — | — | — | 20 | 2,700 |
| Calgary | 1,839 | 43 | — | 50 | — | 38 | — |
| Vancouver | 2,800[b] | — | 86–109 | — | — | — | — |

a. **Appraised value not provided by Transport Canada, so instead the figure is the average value for farmland in Nova Scotia estimated by Statistics Canada, Agriculture Division.**

b. **1 000 hectares assumed available for alternative development, to preserve wetland.**

It can be seen that land for "commercial" purposes has the highest value: this would be land with excellent access — probably on an arterial road — with potential for development of shops, hotels, and so on. It is therefore a very limited proportion of the land on any airport site, and its appraised value is probably dependent on the traffic attracted by the airport. As such, it is inappropriate as a measure of the opportunity cost of the airport land, that is, value in alternative use if the airport were not there.

---

[1] Personal communication between Royal Commission staff and staff of Transport Canada Airports Group, March 1992.

The light and heavy industrial land designated as "with air-side access" is close enough, and on direct roadways to the air-side land, so that it could be used for services for the airlines and aircraft. ("Light industrial" use would include hangars, flight kitchens, fuelling, de-icing; "heavy industrial" use would be rare, including, for example, oil tank farms.) Such land therefore has a premium value over industrial land without air-side access, which can presumably be used only for the same purposes as equivalent land outside of the airport. The appraised value of this land without air-side access therefore gives an indication of the value of the land in industrial use if the airport were not there.

The appraised values of land for agricultural use are clearly much lower than values for the other purposes. Much airport land is apparently usable for farming, and large parts of some airports are currently leased for it — particularly Edmonton, but with sizeable portions also of Calgary and Winnipeg airports.

The appraised values do not include residential use as a current option, but it should be considered in seeking the opportunity cost of the land. Abandonment of the airports (or shifting them to more remote locations) could make available large tracts of land close enough to the centres of some cities that they would be attractive for residential purposes. Even though some of the sites are surrounded by light industrial or heavy-industrial activities, they are sufficiently large that they could be developed as residential enclaves.

In fact, they could become very large residential developments. Table 3(2)-A3 shows the number of houses that could be built on some of the airports, if there were only about 12 houses to the hectare (five to the acre) — which assumes only about half the available land would be house-lots, with the rest used for services, institutions, and so on.

About 20,000 houses could be built on the land area of each of Dorval, Pearson or Calgary airports, about 25,000 on Ottawa's site, or about 35,000 on that in Vancouver. Table 3(2)-A3 also shows the value of this land at the average price estimated for the relevant cities (estimated as described earlier for the value of highway land, assuming serviced land accounts for 30% of new house prices, obtained from Canada Mortgage and Housing Corporation).

*Table 3(2)-A3*
*Value of Airports if Developed for Residential Use, 1991*

| | **Number of houses at 12 per hectare (approx)** | **Value of residential land ($ per hectare)[a]** |
|---|---|---|
| Dorval | 20,000 | 300,000 |
| Pearson | 20,000 | 900,000 |
| Ottawa | 25,000 | 400,000 |
| Calgary | 22,000 | 500,000 |
| Vancouver | 32,000[b] | 700,000 |

a. **Based on estimated values per serviced lot provided for cities from Canada Mortgage and Housing Corporation; reduced by $10,000 per lot as a rough allowance for servicing.**

b. **Only 1 000 hectares assumed available for development.**

If entirely used for residential development, the areas of Pearson and Calgary airports would apparently be worth more than for light industrial use, at about $1.5 billion and $0.9 billion respectively. The sites at Ottawa ($0.8 billion), Vancouver ($0.7 billion) and, in particular Dorval ($0.5 billion) would, by these simplistic calculations, apparently be worth less in residential than in light industrial use.

It should be noted also that these developments would be so large that they would certainly affect the price of housing, and residential land, even in the three largest cities. They might be impractically large, depressing prices so much that the development would only be viable if spread over many years. In cities of the size of Ottawa or Calgary it would certainly not be viable to add so much housing in the short term (25,000 houses would probably add 15% to 25% to the total number existing in Ottawa). Therefore it is probably unreasonable to assume residential development as the opportunity use of the entire area of any of the major federal airports.

For illustrative purposes, Table 3(2)-A4 shows the hypothetical value of the area of each of the airports in possible alternative use. The estimates are very rough, given the uncertainties in the estimated average values per unit of land by purpose, and particularly the reasoning on alternative uses. The reasoning is as follows:

- The sites at Halifax, Mirabel and Edmonton are sufficiently distant from other centres of activity that the possibility of attracting industrial or commercial activity to fill their sites is remote, and farming seems the more reasonable option (and even that might be optimistic for Halifax, or for the entire site of Mirabel).
- For the other airports, it seems likely that some portion of the land could find alternative light industrial use. For Ottawa, Winnipeg and Calgary, the airport areas would add so much land to that available for light industrial use within those cities that it would be very unlikely that the whole area would be developed. There is substantial land available of similar quality, at similar distances from the city centres in each of those communities. It is assumed that 25% of the areas of these airports could be sold at the current price for light industrial land (or, more precisely, that at each of the sites a value equivalent to the current price multiplied by 25% of the surface area could be realized if an attempt to sell the entire area was made).
- For Dorval and Vancouver it is assumed that land so accessible to the city is in sufficient demand that most or all of their usable surface could be turned to light industrial use. The amount of land concerned would still be a significant addition to total light industrial land available even in those regions, so it can be expected that making these tracts available would lower the market price, to some extent. To allow for the interaction of the amount available and its price, it is assumed that the maximum value obtainable from these sites is 50% of their surface area[2] multiplied by the current price — representing, for example, being able to find buyers for 50% of the area at current prices, or lowering the price by 50% in selling the entire space immediately.

---

[2] It is also assumed that only 1 000 hectares of the Vancouver site would be available for development, the remainder being conserved.

- For Pearson, it is assumed that the alternative use is residential, and that a value equivalent to 50% of the current lot price could be realized if the entire surface area was sold.

*Table 3(2)-A4*

*OPPORTUNITY COSTS OF LAND AT MAJOR AIRPORTS, 1991*

| Airport | Estimated land values ($ millions) |
|---|---|
| Halifax | 1 |
| Mirabel | 10 |
| Dorval | 400 |
| Pearson | 750 |
| Ottawa | 440 |
| Winnipeg | 130 |
| Edmonton | 8 |
| Calgary | 200 |
| Vancouver | 500 |
| **Total** (rounded) | **2,500** |

**Value of Land at Other Airports**

Transport Canada has also provided the surface areas of another 87 airports (without any information on their appraised values). The land used for many minor airports has little opportunity cost, in that equivalent unused land is available close to many of the cities and towns concerned. On the other hand, similar land, close to the larger centres, could be very valuable in alternative use. To represent the possibilities, without any site-specific information, it has been assumed for the 20 next-most-important airports, comprising "Class III" in the study for the Royal Commission of airport costing,[3] that the average value of the land at these sites is half the average for the seven Class II major federal airports (that is, the nine airports in Table 3(2)-A4 except Pearson and Vancouver, which form Class I). From the above analysis, the average value per hectare for those seven was $67,000. The average assumed for the next 20 is therefore $33,500 per hectare. Their total area is 12 319 hectares, so the total is $411 million. Added to the median value of the nine major airports, the total then becomes $2.9 billion.

---

[3] Sypher : Mueller International Inc., *Air Infrastructure Costing*, a report prepared for the Royal Commission on National Passenger Transportation, RR-04, August 1991.

For all remaining airports, the value of the land is assumed to be negligible (especially given the margin of error in the above estimate).

### Annualized Value of the Land

The total capital value estimated above is about $2.9 billion. Using a real rate of 10% per year as the opportunity cost rate for capital assets, this land cost is estimated at $290 million per year.

### Land Value per Passenger-Trip, and Passenger-Kilometre

Averaged over a total of 62,813,444 enplaned/deplaned (E/D) passengers at all airports in 1988, the total land value would then amount to some $4.60 per passenger. For the illustrative costs in 1991, this is rounded up to $5 per E/D passenger, or $10 per stage. Averaged over the representative air trip of 1 478 km with 1.6 stages, it amounts to 1.08¢/pass-km, included in the system-wide average costs as 1¢/pass-km.

# 1. RUNNING RIGHTS AND JOINT TRACK USAGE

This section provides a more extended discussion of existing arrangements under which one railway company uses another railway company's track, as a supplement to the subsection of Chapter 6 in Volume 1 entitled "Improving Access to Rail Tracks."

## 1.1 GENERAL

Running rights and joint operations have a long history both in Canada and elsewhere, and are considered by some to be residual customs from early railway development in England. Today, sharing sections of track owned by another railway company is both common and beneficial. Running rights and joint operations not only provide railway companies with access to another company's lines, but can also provide alternative transportation services for railway customers. In Canada, with its difficult geography, such alternatives are very important — when a railway's track is temporarily closed through accident or for major maintenance, trains are routinely routed over a competitor's line.

In some instances, the sharing of facilities is brought about by the need to connect two pieces of track. At the root of this sharing is a desire to avoid unnecessary duplication of railway facilities. Running rights can permit a railway company without its own track to operate successfully. Although it does have small track holdings, VIA Rail essentially operates in this way.

There is a technical difference between running rights and joint operations (or joint track usage). A railway company may have the right to operate trains over the tracks of another railway without any reciprocal (running rights) privilege for the second railway. Joint operations (joint track usage) involve railways sharing facilities in order to improve service or to avoid the duplication of facilities. In Canada, situations range from the example of one railway operating trains for a few hundred feet using another's tracks in order to connect to its own track (running rights), to the proposal that CN and CP jointly use track in the Fraser River canyon. This proposal was made (but never implemented) 10 years ago[1] when double digit traffic growth was forecast.

Running rights and joint track usage complicate the technical operation of a railway. This is most obvious where freight and passenger services are combined. The problem is largely one of operating logic (and perhaps union agreements, where crews are paid on the basis of distance rather than time). Passenger trains accelerate faster and generally operate at faster speeds than freight trains. Also they are usually given higher priority. Problems with scheduling and signalling, especially road crossing protection, can be encountered.

In Canada at the moment, perhaps the most complex operational situation exists between Hamilton and Toronto, where one double-track line serves CN, CP, VIA Rail and GO Transit. This example falls somewhere between the simple running rights example and the Fraser River canyon example, and could be considered joint operations, since the construction of duplicate facilities has been avoided.

## 1.2 LEGISLATION AND REGULATION

### 1.2.1 Canada

Legislation concerning access to trackage of another company has been in the *Railway Act* for many years[2] and remained largely unchanged from the 1919 Act until the proclamation of the *National Transportation Act, 1987* (NTA, 1987).[3] When the NTA, 1987 was drafted, most of the provisions concerning the use of facilities belonging to another railway were taken from the *Railway Act* (section 134) and placed in Part III, Division I of the NTA, 1987, which only deals with freight (see Annex 1). Previously, section 134 of the *Railway Act* had applied to both freight and passenger rail; however, section 94 of the *Railway Act* (1970) remains intact (renumbered section 98) and provides for running rights or joint track usage if the directors of the respective companies agree.[4] The regulatory body's power to order a railway to permit a passenger operator on its lines appears to have been removed, since section 98 (formerly 94) merely provides for agreement by the respective carriers.

The NTA, 1987, section 148 provides for mandatory running rights. Reviewing how it has been applied (for freight) is instructive. The National Transportation Agency recently granted an organization that owns no track (known as MOQ Rail[5]) the status of a railway company under section 11 of the *Railway Act* as amended in 1987. The requirement for this status is similar to that for freight motor vehicle undertakings — a certification of fitness. In May 1990, MOQ Rail applied to operate under the provisions of the NTA, 1987, section 148, over CN lines between Moncton, New Brunswick, and Windsor, Ontario. Tests for a prototype operation (prior to certification under the *Railway Safety Act*) were planned; however, MOQ's application was withdrawn when CN purchased 50% of the company.

### 1.2.2 United States

In the United States, if Amtrak can demonstrate the need to operate over a section of line and can demonstrate that the line is inadequate for passenger operations, the Interstate Commerce Commission (ICC) can require the owning railroad to sell the line to Amtrak for an amount set by the ICC under the provisions of the *Rail Passenger Services Act of 1970* (45 USC 562(d)). As of early 1992, a case was pending before the U.S. Supreme Court that challenged the ICC's enforced sale to Amtrak of a line owned by Guildford Transportation, which owns and operates the Boston and Maine and the Maine Central Railroads. In this instance, Amtrak upgraded the line and then sold it to one of Guildford's competitors.

When Amtrak was established, several lines in the northeastern United States were conveyed to it, while in other areas, it operated over shared facilities. For example, Amtrak at one time operated through the Detroit to Windsor tunnel without paying for the use of the facilities and ran over the Canada Southern (then controlled by

ConRail) across southern Ontario to Niagara Falls. It picked up and carried Canadian passengers between Canadian points and did not pay for the use of the Canada Southern line. It neither sought nor received formal authority from the Canadian Transport Commission to operate on that [illegible] Furthermore, the tunnel was a subsidiary of the Canada Southe[illegible] Canadian company. Amtrak subsequently terminated the service and CP and CN purchased the Canada Southern, the tunnel and the railway bridge at Niagara Falls.

With respect to freight operations in the United States, the ICC has often ordered joint facility usage, especially in yards, when mergers have taken place. Running rights and access to yard facilities have been ordered to ensure that a railroad can connect its various segments of track, and that it can reach connecting carriers.

## 1.3 COMPENSATION

Canadian statutes are silent on the matter of compensation. There are several accepted methods of compensating a railway for the use of its facilities, and these are largely determined by the type of usage made and the privileges accorded to the user railway. There does not appear to be any impediment to two parties developing their own method of compensation based on the nature of the agreement.

In the simplest example — of using a very short stretch of track — the compensation normally consists of installing and paying for the connection(s) and sharing the maintenance costs of the short section of track. In other circumstances, if the host railway only permits the user to run over its line without picking up or delivering freight or passenger traffic, compensation normally consists of what is known as wheelage — that is, a fixed amount per car or locomotive that runs over the line. If the user is allowed to solicit business along the host line, compensation may be a percentage of the revenue generated by the user railway (for example, CP's arrangements for running over CN lines between Port Colborne and Welland).

## 2. BENEFITS AND COSTS OF GREATER SPECIALIZATION IN TRACK USE FOR FREIGHT AND PASSENGER SERVICES ON THE TORONTO–OTTAWA–MONTREAL TRACK NETWORK — A PRELIMINARY ANALYSIS

The subsection of Chapter 6 in Volume 1 entitled "Should a Separate Rail Track Agency be Public or Private?" notes the possibility of rationalizing track use in the Toronto–Ottawa–Montreal triangle. Chapter 18 notes that faster service on some passenger rail routes might be an element of development of some viable rail services. One suggestion presented to the Royal Commission was that dedicating one of the existing Toronto to Montreal rail lines to passenger rail might allow significant improvements in train speed, especially if accompanied by some track upgrading. The Royal Commission did not attempt any thorough evaluation of this suggestion — such an evaluation is the task of managers of passenger rail operations who, under the Royal Commission's framework, would have the main responsibility for judging whether such initiatives might be commercially viable. Some preliminary analysis, however, was carried out that may be of interest to those concerned with passenger rail possibilities.

This note considers the potential for the three class-1 railways — CN, CP and VIA Rail — to reorganize their infrastructure to deliver better rail services, and to do so more efficiently, through consolidating freight operations on one of the main line systems and dedicating the other to passenger service or, more likely, optimizing it to the requirements of passenger service. Any such change would require line upgrading and there could also be regulatory requirements to overcome.

### 2.1 GENERAL CONCEPT

Achieving a substantial degree of specialization of the intercity track in the Toronto–Ottawa–Montreal triangle in either freight or passenger operations might require a single track authority. This note, however, does not concern itself with such possible institutional reform, but rather explores cost aspects of greater specialization in track use that would be relevant whatever the institutional arrangements.

From the passenger service point of view, potential benefits would arise out of:

(a) redistribution of the freight traffic on the existing lines so as to provide one Toronto to Montreal route that could be "optimized" for intermediate speed passenger operations; and

(b) any further arrangements that would help minimize the extent to which competing freight and passenger traffic were at odds.

The concept, as examined here, is not necessarily designed to result in one of the two principal rail rights-of-way becoming a "passenger-only" line, with all of the freight being shifted to the other line. The creation of a passenger-only track — especially using the present CN's Lakeshore route — could result in significant freight access problems and harm to local industry. Rather, the focus is on a system where one route would be optimized for, and carry, the passenger traffic and the other optimized for, and carry, most of the freight.

## 2.2 REQUIREMENTS FOR A UNIFIED SYSTEM OF TRACK

To achieve a workable collective or separated track operation, a blend of technical and operational changes would be necessary.

On the technical side, the CN and CP Toronto to Montreal tracks would need to be connected in four or more locations to allow reasonably convenient access from the northern, predominantly freight track (the present CP mainline) to freight yards and shippers to the south (on the present CN line). There would need to be fully automated, interlocked crossovers that allowed movement between the tracks at reasonable speeds. There are many points where such crossovers could be located. (See subsection 2.3.)

The second major technical change would be a requirement for an integrated signal, train control, and dispatching system for the two tracks, which could be tied into the individual CN and CP systems at each end. The integrated control system should not present insurmountable difficulties, especially since both railways have shown serious interest in the implementation of Advanced Train Control Systems (ATCS).

Other issues needing resolution would include redefining crew districts and seniority systems to reflect the different routing some of the freight trains may take, plus training freight train crews for the additional route. Both railways have successfully negotiated such issues in the past as a result of other structural changes in the railway system. It would also be necessary to develop some changes in the way liability for accidents is assessed. Again, CN, CP and VIA Rail have operated with running rights over parts of other railway systems and have developed methods of dealing with the issue.

Another issue that must be addressed is the capacity of the one route — in this discussion, the CP track — to efficiently handle the additional freight traffic displaced from the other route. In general, the capacity appears to exist, but there could be degradation of express-train trip times — which both CN and CP may find unacceptable for market reasons. Additional siding capacity would be needed on the single-track section between Toronto and Smiths Falls. Without simulation of the train configurations and dispatch times, it is difficult to predict the extent of the additional capacity requirements.

## 2.3 FREIGHT ACCESS

The development of satisfactory freight access from the present CP mainline to the present CN Lakeshore track seems possible at the cost of investing in new connections. Freight access is not as much of an issue on other segments of the "triangle." VIA Rail is the only user of, and has purchased, the Smiths Falls to Ottawa segment of the track. Between Brockville and Smiths Falls there is presently very little freight traffic, and this is unlikely to interfere with the passenger trains. On this segment, most passenger delays are due to the transition between the two routes at Smiths Falls. Thus, greater specialization of track use, in itself, could not be expected to be of any significant benefit to the passenger system; a by-pass or new connecting tracks would be required to make any noticeable improvement. (This has not been included in the notional cost estimates that appear later.)

On the Ottawa to Montreal route (CN's Alexandria Subdivision), there is little opportunity to provide alternative freight access for local traffic. The line also carries Ottawa to Montreal freight trains and some freight trains between western Canada and Montreal. There is alternative routing from the Lakeshore track to Ottawa via the CP Prescott Subdivision, and traffic from western Canada can be rerouted via CP's mainline through Smiths Falls.[6]

It should also be noted that VIA Rail presently owns most of CP's old M and O Subdivision right-of-way that runs from Ottawa to Dorion. The track has been removed from this route. While this would be a straight and direct route for passenger service, it would require new track at substantial cost.

## 2.4 BENEFITS OF REDUCED FREIGHT INTERFERENCE

It is sometimes suggested that reducing the number of freight trains on the Lakeshore track could create a significant benefit in improved passenger trip times since there would be less interference between freight and passenger trains. This is not likely to be the case. First, much of the CN freight traffic is scheduled at night and other times when there are no passenger trains, and some daytime freight trains do not operate on an express schedule, instead waiting for the passenger trains. Second, the Lakeshore route is a full double-track system with a significant siding capacity, which reduces freight and passenger interference.

In overall terms, our investigations suggest that there is little freight interference delay built into VIA Rail's present express-train times between Toronto and Montreal. If anything, there may be more interference between individual passenger trains at station stops.[7] Other potential interference between the freight and passenger systems is more incidental and can be eliminated or reduced without restricting the number of freight trains.[8] On average, reducing freight-passenger interference by restricting the number of freight trains on the Lakeshore route could only shorten the passenger-trip time by a few minutes — because mainly through-freight (which interferes little) could be shifted to the CP route, and the present level of way-freight activity (which interferes more) would continue.

Of more benefit may be the potential for greater schedule flexibility (arrival and departure times) that might be gained through reducing the number of freight trains on the Lakeshore route. However, this type of freight and passenger interference often takes place in urban areas and at other points where geography limits the potential for reducing the number of freight trains. For example, eastbound CN freight access from the Montreal yard over the Victoria Bridge to the Maritimes appears to be one of the governing factors in the scheduling of passenger trains into and out of Montreal's Central Station. Given the importance of the timeliness of these trains to the Halifax container terminals, competing against Montreal and U.S. rivals, there is only limited flexibility here.

## 2.5 BENEFITS OF HIGHER SPEED LIMITS

Given the present demands on the transportation system, greater potential benefits from the creation of a "passenger-optimized" Toronto to Montreal route may result from raising the passenger train speed limit. At present, with a mix of freight and passenger trains — operating over level crossings at quite different speeds — the passenger train speed limit is 95 mph (153 km/h). Steps that might be taken to improve passenger train trip times include adjusting crossing signal timings to safely allow higher speed operation through grade crossings, and resetting curve super-elevations more in line with passenger train speeds.

How much and what type of freight remains on the passenger-optimized line will be important. Assuming that higher speed operation through grade crossings is considered reasonable — Amtrak allows 110 mph (177 km/h) operation through grade crossings in the Northeast Corridor — it would be necessary to reset all of the grade-crossing protection circuits to provide the necessary warning time at higher speeds. Presuming some freight traffic is to be retained, it would be advantageous to provide some form of "smart" grade-crossing circuits that would detect the difference in train speeds and provide the appropriate warning time. (Imposing a long wait on motorists for a slow freight train undermines crossing signal credibility, and encourages motorists to take risks.) The technology for smart grade crossings is available, but its installation could be expensive.

Resetting curves would allow passenger trains to negotiate them at a higher speed, but curves cannot be fully optimized for passenger service if freight traffic is to be continued. While there are curves on the Lakeshore route, it is not overly curvaceous. Thus, the potential gains in trip time will be limited. On the other hand, if one were prepared to wait, the cost of resetting curves would be modest, since much of this work could be carried out as part of the routine and scheduled track maintenance programs.

In terms of the signal system itself — for protecting following and opposing train movements — preliminary investigations do not suggest that much additional investment would be required to allow higher passenger train speeds within the range that is being considered. It appears that present block lengths and stopping distance allowances would be sufficient to allow 105 mph (170 km/h) or higher operation in many of the non-urban areas of the Lakeshore route.

How much time could be gained on a Toronto to Montreal trip? VIA Rail's present best trip time with an F-40 locomotive and four LRC cars is 4 h 10 min with an intermediate stop only at Dorval. For every 5 mph (8 km/h) gain in the average achievable speed in the non-urban areas (roughly Pickering to Dorval), approximately 10 minutes could be taken off the trip time. A 20-minute improvement in trip time might be achievable — perhaps a bit more — without substantial investment (more than estimated in subsection 2.6). In addition, there appear to be other modest investments that would result in a savings of trip time. What is not at all clear is how much of the overall time savings may be achievable within the present context, and how much might require the shifting of freight traffic.

An important issue in improving train speeds on the Lakeshore route that is often overlooked is the capabilities of the rolling stock itself. The LRC locomotive has been tested to speeds as fast as 125 mph (200 km/h), although neither CN nor VIA Rail would want to operate such a heavy locomotive at that speed. The newer F-40s have been cleared to operate at 95 mph (153 km/h). It is not known how much more speed can be gained from this equipment. What is clear is, however, that going to much higher speeds would require the shortening of the trains or adding a second locomotive. Under present circumstances, the addition of even one car to a four-car LRC-powered train would result in a noticeable performance degradation if run to VIA Rail's fastest schedule. The potential need for more powerful locomotives, or for a second locomotive unit, will have to be included in any analysis of the gains from increased speed. In many cases, the second locomotive may already be available in the present (or projected) fleet to handle peak train sizes; it simply is not used on days when demand dictates a shorter train.

## 2.6 NOTIONAL CAPITAL COSTS FOR AN INTEGRATED SYSTEM

In terms of infrastructure investment, costs of a general order of $60 million would be required to interconnect the two systems substantially to allow ease in rerouting intercity freight trains and faster passenger-train operation. The following are the types of investment required:

*Table 6(2)-1*

*COST OF INVESTMENTS FOR AN INTEGRATED SYSTEM*

| **Investment** | **Notional cost** |
|---|---|
| Provision of interconnections between CN and CP main track | $15 million to $20 million |
| Provision of new signal interlockings and consequent changes | $15 million to $25 million |
| Alteration of grade-crossing circuits (Lakeshore) | $10 million to $20 million |
| Improvements to CP main track | about $5 million |
| **Total** | **$45 million to $70 million** |

## 2.7 NOTIONAL TRACK OPERATING AND MAINTENANCE COSTS

An examination of VIA Rail's cost data indicates that approximately $15 million is paid annually to CN and CP (mostly CN) for use of the track between Toronto, Ottawa and Montreal as defined in the subject network. This figure is higher than that paid under the basis of estimated system-average variable unit cost, which was used in the past for determining compensation to the freight railways for passenger train use. It reflects an acceptance of the propositions that:

- the passenger service constitutes a substantial component of the traffic between Toronto and Montreal, and accounts for costs that would not be avoidable under most Canadian passenger-rail circumstances;
- for track for which VIA Rail is sole user, it must pay the total (not just the variable) cost;
- the costs of maintaining a track for higher than average speed passenger operations are higher than average; and
- incentive payments for service can be effective where regulatory compulsion fails.

CN's and CP's total cost,[9] not including corporate overhead, of maintaining and operating track in this network is about $75 million per year. (This amount includes the cost of train dispatching; the area includes the links to Ottawa.)

## 2.8 ATTRIBUTION OF COST

Shifting the proportions of freight and passenger to concentrate freight on the CP line would result in a larger proportion of the present CN track costs being attributed to the passenger system, especially that portion of the costs independent of traffic levels. Routine rail replacement and other maintenance requirements for the track specialized for passenger use can be expected to decrease simply because of the decreased traffic levels.[10] At the same time, higher passenger speeds would cause increased unit costs from:

- increased track damage due to dynamic loads; and
- tighter track (line, level and gauge) tolerances.

Presumably the track would be priced on the basis of the value of the service provided; traffic that could not cover its marginal cost would not be accepted. Estimates of service value and marginal cost are far beyond the scope of this very preliminary exploration; however, two cost allocation possibilities — essentially limits within which true causality should fall — are shown in Table 6(2)-2.

*Table 6(2)-2*
*ALLOCATION OF NOTIONAL TRACK OPERATING COSTS*

| | Proportion of traffic | | Allocated cost | |
|---|---|---|---|---|
| **Allocation** | **Tonne-km (%)** | **Train-km (%)** | **Tonne-km ($ million)** | **Train-km ($million)** |
| Passenger | 11 | 40 | 8 | 30 |
| Freight | 87 | 57 | 65 | 43 |
| Commuter | 2 | 3 | 2 | 2 |

Table 6(2)-2 does not include any charges for administration of a track operating authority or for necessary capital investment. Nor are GO Transit's track ownership or maintenance costs considered. It will be seen that annual operating costs allocated to passenger rail could well exceed current VIA Rail payments for track use by $5 million to $10 million. In addition, some portion of the roughly $60 million in one-time capital costs should be attributed to the passenger rail service. Track specialization, and the modest investment in track upgrading for passenger-only use, might improve the time of the faster Toronto to Montreal train from 4 h 10 min to about 3 h 30 min.

# ENDNOTES

1. This proposal considered joint CN and CP operations in the Fraser Canyon with westbound trains using CN tracks and eastbound trains using CP tracks. De Leuw Cather Canada Ltd., *Joint Track Usage Study: Kamloops–Mission B.C.*, November 1985.

2. An early reference to *running rights* appears in the *Railways Clauses Consolidation Act,* (8 Vict. c.20) of 1845 (British). Much Canadian railway legislation was patterned on this statute.

3. The running rights provisions in the *Railway Act* and the NTA, 1987 only apply to federally incorporated railways (this includes U.S. railroads connecting into Canada). The National Transportation Agency can order a federal railway to permit a connection with a provincially incorporated railway.

4. Recommendation by the National Transportation Agency and sanction by the Governor in Council are also required.

5. MOQ Rail is developing a prototype operation using highway type trailers fitted with both highway type wheels and steel rail type wheels. The motive power would be provided by highway style cabs. The trailer concept has similarities to the successful RoadRailer system operated by Triple Crown (a subsidiary of Norfolk Southern) in the United States. The motive power is a new departure.

6. Such a scheme for trains to and from western Canada has been discussed for many years and may have benefits for CN and CP independently of any passenger system benefit.

7. For example, four passenger trains stop at Kingston during a half-hour period on weekday mornings. Often, one or more of these trains must wait for one of the other passenger trains to clear the station.

8. For example, at Brockville, additional delay is sometimes incurred because there is direct foot access to only one track, and there is no physical barrier between the two main tracks. Providing a passenger underpass or overpass, and building a fence between the tracks would eliminate some of the problems here.

9. Operating cost and sustaining capital.

10. The counterpart to much of this savings would be increased replacement and maintenance requirements for the CP track to which the freight traffic would be shifted.

# ANNEX 1

## THE *NATIONAL TRANSPORTATION ACT, 1987*

Provisions of the *National Transportation Act, 1987* (NTA, 1987) dealing with running rights and joint track usage are under the title Railway Freight.

- Section 148 authorizes the National Transportation Agency to direct one railway company to provide access to another and to set the required amount of compensation the user must pay. The Agency may exercise this power where the two companies cannot reach an agreement and rail access is deemed to be in the public interest.
- Section 149 authorizes the Governor in Council, after specified process, to order common use of a railway right-of-way and fix the amount of compensation to be paid for that common use.

Presumably such provisions apply solely to freight. There is no obvious reason why they should not also be made applicable to passenger rail.

Subsection 174(6) provides that when a railway line is transferred from one railway company to another, the selling railway is relieved of its obligations related to the operation of that line under the NTA, 1987 or any other Act of Parliament. However, when VIA Rail has an existing operation on a line sold by a federal company to another company (either federal or provincial), the line remains under federal jurisdiction. The acquiring company inherits all the obligations of the selling company, including those under the *Canada Labour Code,* for example, the selling railway's collective agreements.

If a line with VIA Rail service transferred from one company to another is then abandoned, or VIA Rail service is discontinued, the line is no longer deemed to be a work for the general advantage of Canada and may be transferred out of federal jurisdiction.

# 1. INTRODUCTION

The Royal Commission's considerations of environmental issues were aided by two pieces of contracted research. The first is by VHB Research & Consulting Inc., "Environmental Damage from Transportation," published in Volume 4 of this report,[1] which summarizes the nature and effects of environmental damage, and provides estimates of air pollutant emissions by intercity passenger mode in Canada. It also considers the practicality of methods of assessing the social costs of environmental damage, and offers some estimates of the costs of air pollution per mode. In view of its availability in Volume 4, only the briefest summary of the effects will be provided in these notes.

The second piece is by William A. Sims, "Externality Pricing," which is distributed as RR-07 in the series of reports prepared for the Royal Commission.[2] It reviews the theoretical case for direct pricing of such externalities as environmental damage, from the economic literature. The policy issues in charging for environmental damage, or otherwise approaching damage mitigation through economic incentives/ disincentives, are also reviewed thoroughly in a Government of Canada paper that became available during the Commission's deliberations, *Economic Instruments for Environmental Protection.*[3]

## 1.1 MAIN ENVIRONMENTAL EFFECTS

The environmental effects of passenger transportation that are of main policy concern are:

- air pollution;
- global warming; and
- noise.

Another important environmental effect is the disruption of local communities by transport infrastructure and traffic.

These effects all cause harm to natural ecosystems or to people or communities, but harm that is outside our normal system of markets. Thus, it is unpriced, failing to appear as a cost to the transport carrier or passenger. These effects also all differ spatially, seasonally and by time of day. A pricing system that incorporated these "externalities" in decisions about infrastructure investment and use would (at least to some extent) reduce the extent of transportation, and cause shifts toward those modes of travel, locations and times that would cause less environmental damage.

Most of what follows in these notes refers to air pollution and global warming because those are the effects for which most information is available. It is anticipated that a policy framework dealing with these effects should also apply to noise and community disruption; some relevant policy aspects of the damage are mentioned below.

## 2. EMISSIONS FROM ENGINES AND VEHICLES

### 2.1 EMISSIONS OF MAIN CONCERN[4]

#### 2.1.1 Volatile Organic Compounds

Volatile organic compounds (VOCs) include the volatile hydrocarbons of unburned fuel in exhaust gases, or evaporated from engines and gas tanks (and filling stations). These are of concern primarily because of their contribution to the formation of low-level ozone (discussed later). About 40% of all VOCs from non-natural (man-made) sources originates from transportation.

#### 2.1.2 Nitrogen Oxides

Oxides of nitrogen ($NO_x$) are fuel combustion by-products, formed particularly at high engine temperatures, and, therefore, disproportionately by diesel engines. Nitrogen dioxide ($NO_2$) is of concern because it can cause harm to health and damage to vegetation, and it reduces urban visibility (forming the brown haze on hot days in large cities). Through chemical conversion, $NO_x$ also contributes to the formation of ozone and of nitric acid, a component of acid rain. Transportation is responsible for about 60% of all non-natural $NO_x$ emissions.

The most important, and complex, role of transportation $NO_x$ is in the formation of ozone. This gas is important to the environment in two very different ways. More familiar to the public is the "ozone layer" in the high atmosphere, which acts as a reflective screen against solar ultraviolet radiation, preventing harmful amounts of radiation from reaching the Earth's surface, where they would add to global warming and increase skin cancer. The concern is that this layer is being depleted through artificial disruption of natural processes.

Quite the opposite concern is expressed when ozone exists in the atmosphere close to ground level, where its effects are harmful rather than beneficial. Low-level ozone is formed from chemical conversion of $NO_x$ in sunlight, with VOCs aiding the reactions. Non-natural emissions are partially responsible, including those from transportation. This "low-level" ozone can be transported downwind, but breaks down through further chemical processes within hours or days. Concentrations increase over cities with high $NO_x$ and VOCs emissions, particularly in summer, in "episodes" that last a few days. Effects can be felt over regions encompassing groups of cities arranged along the direction of the prevailing air currents, and over the intervening rural areas.

Ozone concentrations are greatest in three regions of Canada: the Lower Fraser Valley of British Columbia; the "corridor" between Windsor, Ontario, and Quebec City, Quebec; and in the area of Saint John, New Brunswick. Ozone originating from adjacent U.S. industrial areas is largely responsible for the concentrations in the latter region, and contributes substantially to concentrations in southern Ontario and Quebec.

Potential harmful effects of low-level ozone include respiratory problems and damage to foliage of crops and trees. Furthermore, ozone in the lower atmosphere itself acts as a "greenhouse gas," absorbing heat radiated from the Earth and adding to global warming.

The low-level ozone is effectively unconnected to the high-level "ozone layer," so the Earth faces simultaneously an excess of ozone in the lower atmosphere and depletion in the upper atmosphere.

The contribution of transportation $NO_x$ to ozone formation, as well as its effects, depends on the altitude at which the emissions occur. As the great bulk are at ground level (from motor vehicles, trains and ships), the main potential problem is the direct damage ozone causes to people and foliage.

Aircraft emissions, however, present different problems. There is increasing evidence that $NO_x$ emitted by aircraft in the high troposphere (at the cruising altitude of modern jets) is particularly potent at producing ozone.[5] That ozone is unlikely to reach people and crops at ground level, but might be adding substantially to global warming. Furthermore, supersonic aircraft operate at much higher altitudes, close to, or even within, the "ozone layer." Paradoxically, their emissions of $NO_x$ at those altitudes do not create ozone, but actually contribute to its depletion. At present, there are very few such aircraft operations, but if the supersonic fleet were to expand greatly, control of their $NO_x$ emissions might become a priority.

### 2.1.3 Carbon Monoxide

Carbon monoxide (CO) is a combustion by-product with potentially serious health effects. About 60% of total non-natural emissions are from transportation, and 75% of transportation emissions come from passenger cars, pick-up trucks and vans.

### 2.1.4 Particulates

Particulates are solid materials in engine exhaust, consisting of about 75% carbon (soot) and 25% "polycyclic aromatic hydrocarbons," which potentially cause cancer. Transportation sources account for only about 1.3% of total non-natural particulate emissions, but a larger portion of the very small particles that are considered more problematic (those less than one hundredth of a millimetre in diameter). Very small particles are emitted more by diesel engines than by gasoline engines or turbines.

### 2.1.5 Sulphur Dioxide

Sulphur dioxide ($SO_2$) is a by-product of burning fossil fuels containing sulphur. It is of concern for its potential direct health effects and also its conversion to form sulphuric acid, the predominant acid in acid rain. Emissions depend on the amount of sulphur in fuels (including how much is removed from oil during refining). The sulphur content of diesel is higher than that of gasoline and aviation fuel, and is greater for marine diesel than for diesel used in motor vehicles or trains. Transportation contributes only about 2.2% of total non-natural emissions in Canada, of which one third is from marine engines. Non-ferrous smelting and thermal power generation provide the bulk of emissions.

### 2.1.6 Chlorofluorocarbons

Chlorofluorocarbons (CFCs) are used as blowing agents, coolants in air conditioning systems and refrigeration in all transport modes, and in foam padding and seats. CFCs are of concern for their destruction of the ozone layer. Motor-vehicle air conditioners have recently contributed about 25% of Canadian CFC emissions; the remainder comes largely from commercial refrigeration and air conditioning. Replacement chemicals are expected to be introduced rapidly in accordance with Canada's announced goal to eliminate CFC use by 1997. (This goal is discussed later in this chapter.)

### 2.1.7 Carbon Dioxide

Carbon dioxide ($CO_2$) is a by-product of combustion of any carbon-based fuel (such as oil, coal or wood), and is of concern as the major contributor to the "greenhouse effect" of global warming. Unlike VOCs, $NO_x$ and CO, which can be controlled by exhaust-treatment techniques, $CO_2$ remains unchanged, and therefore varies directly with the amount of fuel used. About one quarter of total non-natural emissions are from transportation, the bulk of the remainder being from power generation, industrial energy use and space heating. $CO_2$ is released naturally by all plants and animals as a consequence of energy production (as when the body processes food carbohydrates and oxygen into energy, creating waste products of carbon dioxide and water vapour); $CO_2$ is also the result of natural decaying or burning of vegetation, and of volcanic activity.

## 2.2 AMOUNTS OF EMISSIONS BY INTERCITY MODES

Emissions by mode, in grams per unit of fuel used, were obtained from the VHB study for the Royal Commission, reproduced in Volume 4 of this report.[6] Estimates are provided of energy use by mode in megajoules per passenger-kilometre, and of emissions in grams per passenger-kilometre of $CO_2$, $SO_2$, $NO_x$, non-methane hydrocarbons (VOCs), particulates and CO. For intercity passenger travel, and the attempts to cost and price the environmental damage, it is assumed that the crucial emissions are those of $CO_2$, $NO_x$ and VOCs, so the estimates that follow are confined to those.

The estimates of emissions for passenger cars were modified to combine estimates for cars and light trucks, based on light truck emissions of $NO_x$ and VOCs being 20% greater per vehicle-kilometre than car emissions. (This value was derived from weighted national averages of the information in Tables 5 and 6 of the VHB report.) Highway fuel consumption, and therefore $CO_2$ emissions, are estimated to be 33% higher per vehicle-kilometre for light trucks (12 L/100 km versus 9 L/100 km). The combined results appear as estimates for "cars" in the tables.

The estimates of average fuel consumption by mode were also modified by the Royal Commission staff, as discussed in the Notes to Chapter 3. The VHB estimates of emissions by mode have been converted first to grams per megajoule (g/MJ) of fuel, represented in Table 7(2)-1.

*Table 7(2)-1*
*Ratios of Emissions to Energy Use (g/MJ)*

| Mode | $CO_2$ | $NO_x$ | VOCs |
|---|---|---|---|
| Bus | 70.8 | 0.915 to 0.962 | 0.106 to 0.135 |
| Car | 73.8 | 0.388 to 0.482 | 0.488 to 0.599 |
| Train | 70.7 | 1.428 to 1.442 | 0.069 to 0.195 |
| Airplane | 70.8 | 0.045 to 0.174 | 0.030 to 0.037 |
| Ferry | 81.6 | 0.091 to 0.120 | 0.009 to 0.012 |

These are multiplied by estimated system-wide average consumption of MJ of energy, obtained from Royal Commission staff estimates of average fuel use, as in Table 7(2)-2.

*Table 7(2)-2*
*System-Wide Average Fuel Use by Mode*

| Mode | Energy/Fuel (MJ/L) | Amount travelled/ Fuel (pass-km/L) | Energy/Amount travelled (MJ/pass-km) |
|---|---|---|---|
| Bus | 38.68 | 57.8 | 0.67 |
| Car | 34.66 | 18.6 | 1.86 |
| Train | 38.68 | 23.4 | 1.65 |
| Plane | 37.68 | 9.7 | 3.88 |
| Ferry[a] | 38.68 | 5.2 | 7.39 |

**a. See endnote 7.**

Then multiplying g/MJ by MJ/pass-km gives grams of emissions per passenger-kilometre by mode, as in Table 7(2)-3.

*Table 7(2)-3*
*Estimated Emissions per Passenger-Kilometre (g/pass-km)*

| Mode | $CO_2$ | $NO_x$ | VOCs |
|---|---|---|---|
| Bus | 51.7 | 0.500 to 0.860 | 0.070 to 0.100 |
| Car | 125.5 | 0.659 to 0.819 | 0.829 to 1.019 |
| Train | 116.9 | 2.361 to 2.385 | 0.115 to 0.323 |
| Plane | 274.9 | 0.175 to 0.676 | 0.116 to 1.144 |
| Ferry | 603.0 | 0.672 to 0.887 | 0.067 to 0.089 |

## 2.3 SUMMARY OF KNOWLEDGE OF EFFECTS[8]

### 2.3.1 Health

The federal government has established National Ambient Air Quality Objectives (NAAQOs)[9] for the major pollutants, specifying levels that are the maximum "acceptable," intended to provide adequate well-being and personal comfort. Measurements of pollutants are taken continually by Environment Canada at numerous sites across the country. Interpretation of the results shows that, while there are some potential health problems posed by high local concentrations of CO, $NO_2$ and diesel particulates, none of these is found routinely in concentrations that violate the National Ambient Air Quality Objectives.[10]

A much greater concern is the exposure of people to low-level ozone. Canada's NAAQOs for a one-hour exposure to ozone is exceeded occasionally in most large cities, and regularly so in the Lower Fraser Valley of British Columbia, southern Ontario, the area of Quebec between Montreal and Quebec City, and southeastern New Brunswick.[11] There is evidence that ozone at these concentrations causes breathing difficulties, particularly among asthmatics (5% of the population). Periods of high ozone have also been linked with increases in hospital admissions and use of medication for respiratory problems.[12]

### 2.3.2 Materials

Acid rain can affect building stone and mortar; $NO_2$, nitric acid and ozone can affect paints; $NO_2$ and ozone can affect fabrics; $SO_2$, $NO_2$ and nitric acid can affect metals. But the laboratory demonstrations of these effects are conducted using concentrations far higher than exist in Canada. The VHB research report for the Royal Commission concludes there is "no evidence that existing levels in the Canadian environment adversely affect materials."[13]

### 2.3.3 Forest Resources

Substantial effects of acid rain on germination and survival of tree seedlings are seen only at levels of acidity higher than found in Canadian rainfall, and no definitive trends in responses of forests to ozone have been found.

### 2.3.4 Crops

Effects of ozone in damaging foliage, and therefore crop yields, are well established, with resulting reductions in annual crop values estimated for Ontario at $15 million to $23 million in 1984.[14] $NO_2$ and acid precipitation at Canadian levels are not thought to cause substantial damage to crops.

### 2.3.5 Fish

$NO_x$ deposited as acid rain has adverse effects on life in eastern Canadian lakes. Approximately 150,000 lakes are being damaged, more than 14,000 of which have been described by Environment Canada as "acidified."[15]

## 2.4 GLOBAL WARMING

Scientific concern has increased that non-natural additions of certain gases to the atmosphere increase the atmosphere's retention of radiated heat in a "greenhouse effect" that raises average global surface temperatures. Research has not produced definitive findings on the extent and effects of such warming, so an Intergovernmental Panel on Climate Change was established in 1988, under the United Nations Environment Programme. This panel of scientists reviewed the scientific evidence, concluding:

> We are certain of the following:
>
> - There is a natural greenhouse effect which already keeps the Earth warmer than it would otherwise be.
> - Emissions resulting from human activities are substantially increasing the atmospheric concentrations of the greenhouse

> gases: carbon dioxide, methane, chlorofluorocarbons and nitrous oxide. These increases will enhance the greenhouse effect, resulting on average in an additional warming of the Earth's surface.[16]

The panel predicts that, if no control measures are taken, global mean temperature will rise above pre-industrial levels by more than 2°C by 2050 and 4°C before 2100. Among the important effects, thermal expansion of the oceans and melting ice would raise global mean sea level by about 6 cm per decade.

The Canadian Climate Program Board has predicted that the potential effects in Canada would include:

- a shift of climatic zones several hundred kilometres northward over the next 50 years, significant degradation of permafrost, changes to ecosystems and wildlife habitat at so fast a rate that some species may be unable to survive, disruption to northern indigenous people, and threats to northern buildings and pipelines;
- increased drought risks, especially in the Prairies;
- increased probabilities of forest fire and insect and disease attacks;
- adverse effects on human health from more frequent and intense heat waves in cities, and the northward spread of tropical diseases; and
- an increase in soil erosion, changes to coastal ecology, damage to wetlands and important fisheries, and substantial costs for coastal protection due to rising sea levels.

The Board also suggests there is some potential for northward expansion of agricultural crops where soils permit.[17]

Descriptions of potential global effects are provided in a recent U.S. National Academy of Sciences study.[18] To date, estimates of the costs that would be imposed by the predicted effects have not been made for Canada, and are rare worldwide. Predictions of the effects by sector of activity in the United States lead Nordhaus[19] to suggest that identifiable costs would be equivalent to about one quarter of 1% of national income, and his judgement is that including unmeasured effects and uncertainty puts the upper limit at 2% of national income.

## 3. CURRENT AND ANNOUNCED CONTROL STRATEGY FOR AIR POLLUTION

### 3.1 VEHICLE EMISSION STANDARDS

Control of transportation air pollutants is mostly by federal regulation of limits for emissions from new vehicles, and is essentially limited to road vehicles. Aircraft jet engines are subject to limits set by the International Civil Aviation Organization, to which all Canadian engines conform, even though the standards have no legal force in Canada. No regulations exist for locomotive engines. Ships are subject only to a federal smoke limit, which is a remnant of the coal-fired steamship era.

Motor-vehicle exhaust emissions are controlled by regulations for new vehicle performance under the federal *Motor Vehicle Safety Act*, administered by Transport Canada. The standards were tightened substantially for new cars in 1986 and new trucks in 1988, essentially to be equal to U.S. standards. Those standards in the United States have since been made even more stringent, and plans have been announced by Environment Canada and Transport Canada to "harmonize" with those shortly.[20] Thereafter it is the intention to maintain equivalence with the United States, thus continuing to have the most stringent standards in the world. Those plans also include examining the feasibility of regulating emissions released by aircraft, ships and trains.

Emissions through the lifetimes of motor vehicles are regulated to some extent through the new vehicle standards, which specify performance to be met over a designated vehicle lifetime. Nevertheless, emissions can increase over lifetime through poor maintenance or tampering with emission control equipment. Provincial programs of compulsory periodic emissions testing are proposed in the $NO_x$/VOCs Management Plan for the "ozone non-attainment areas" of southern British Columbia and the Windsor to Quebec City corridor (see description of the Plan, which follows). British Columbia introduced a testing program for cars and light trucks in the lower mainland in September 1992.

## 3.2 ANNOUNCED NATIONAL OZONE CONTROL STRATEGY

### 3.2.1 Multinational Goals

*$NO_x$:* Under the $NO_x$ Protocol of 1988, Canada and 24 other countries are committed to freezing national $NO_x$ emissions at 1987 levels. Canada's strategy is contained in the $NO_x$/VOCs Management Plan.

*VOCs:* By a similar international agreement signed in November 1991, Canada will by 1999 freeze VOCs at 1988 levels, and reduce them by 30% in two areas designated under the agreement as "tropospheric ozone management areas": the Lower Fraser Valley and the Windsor to Quebec City corridor.

### 3.2.2 $NO_x$/VOCs Management Plan

Recognizing ozone as the prime air pollution problem in Canada, the Canadian Council of Ministers of the Environment (CCME) adopted, in November 1990, a Management Plan for $NO_x$/VOCs.[21] The Plan includes a number of new nation-wide regulations, which in the transport sector involve further tightening of motor-vehicle emission standards starting in 1996. In addition, the Plan designates the three Canadian regions that frequently exceed ozone NAAQOs as "ozone non-attainment areas": the Lower Fraser Valley, the Windsor to Quebec City corridor, and the Saint John area. For these, separate targets for $NO_x$ and VOCs reductions are being negotiated with the provinces concerned, and the plan envisages adopting special local control measures. The list being considered initially includes, for the transport sector:

- more rigorous speed-limit enforcement in summer;
- motor-vehicle inspections and anti-tampering laws;
- reduction in summer gasoline volatility; and
- evaporative loss controls at refuelling stations.

The plan includes forecasts to 2005 of expected changes in emissions, based on economic and population growth estimates, National Energy Board (NEB) estimates of energy demand by sector of activity, and demand growth estimates and input fuel mixes for electricity generation provided by provincial power utilities. For road transportation, it includes forecasts of vehicle sales provided by the Motor Vehicle Manufacturers Association, together with NEB estimates of total vehicle fleet size and use (assuming constant annual kilometres per vehicle).[22]

Effects of the Plan were predicted as changes in these forecasts. Some details of the main sources of $NO_x$ and VOCs are shown in Tables 7(2)-4 and 7(2)-5, together with predictions for 2005 with and without the impacts of the new Plan. It can be seen that emissions of both $NO_x$ and VOCs were predicted to increase by about 6% from 1985 to 2005 in the absence of the Plan, as growth in the use of stationary sources outweighed the very substantial continuing reductions in transport sources resulting from already-established motor-vehicle standards. The Plan expects $NO_x$ levels to decrease until 1995 due to a sharp decline in emissions from light and heavy vehicles. This will result from increasing numbers of vehicles equipped with emission controls that meet recent standards, combined with modest reductions in rail emissions. These transportation reductions outweigh increases in emissions from other sectors until about 1995. Thereafter, the increases in motor-vehicle use are expected to offset remaining reductions in average fleet emissions per vehicle-kilometre, so that total national emissions first flatten and then begin to rise slowly as emissions continue to grow in other sectors.

## Table 7(2)-4

## NITROGEN OXIDES EMISSIONS AND PROJECTIONS TO 2005

| Source | 1985 (kt) | Proportion of total (%) | 2005 base case (kt) | Change from 1985 (%) | 2005 with plan[a] (kt) | Change from 1985 (%) |

**[a] After implementation of the measures currently outlined in the $NO_x$/VOCs Management Plan.**

For VOCs, a rapid decline in emissions is also expected from motor vehicles in the short term, outweighing increases in other sectors. Motor vehicles, however, contribute a smaller proportion of total VOCs emissions than total $NO_x$ emissions, and their reductions are expected to be overtaken earlier than 1995 by persistent increases in VOCs from non-transportation sources.

Adopting proposals identified in the national Plan would reduce total $NO_x$ emissions in 2005 by about 11%, and VOCs emissions by 16% over recent levels. The Plan also envisages tightened objectives and extended programs in the future, particularly in the non-attainment areas.

The CCME forecasts that implementing the Plan will substantially reduce peak ozone concentrations and periods exceeding the maximum acceptable NAAQO. In 2005, the annual hours in excess of the latter standard would be halved in the Lower Fraser Valley and Saint John area, and reduced by 20% to 40% in the Windsor to Quebec City corridor, east of Toronto.[23] The improvements are expected to be even greater when combined with announced control programs in the United States. The CCME expects implementation of the amendments to the U.S. *Clean Air Act* to reduce $NO_x$ emissions by 30% and VOCs emissions by 40% to 50% in those regions of importance to Canadian ozone concentrations (the U.S. Eastern Seaboard, the area south and west of lakes Erie and Ontario, and the Seattle area). This reduction will bring important additional reductions in periods exceeding the maximum acceptable NAAQO for ozone in southwest Nova Scotia and throughout the Windsor to Quebec City corridor, particularly to the west of Toronto.[24]

## 4. GLOBAL WARMING AND CANADA'S PROPOSED ACTIONS[25]

### 4.1 GREENHOUSE GAS EMISSIONS IN CANADA

Minor transport contributions to global warming arise from CFCs in automobile air conditioners and methane from natural gas distribution. Low-level ozone, to which transport emissions of $NO_x$ and VOCs contribute, also adds to the greenhouse effect. All such contributions are dwarfed by transport emissions of $CO_2$ from burning carbon fuels.

#### 4.1.1 Carbon Dioxide

Emissions of $CO_2$ in 1990, and projections for the years 2000 and 2010, are shown in Table 7(2)-6. It will be seen that transport accounts for about 25% of the Canadian total of some 520 Mt, with road vehicles alone responsible for about four fifths of the transport contribution, or 20% of the total.

*Table 7(2)-6*
CARBON DIOXIDE EMISSION PROJECTIONS 1990–2010[a]

| Source | 1990 (Mt) | Proportion of total (%) | 2000 (Mt) | Change from 1990 (%) | 2010 (Mt) | Change from 1990 (%) |

| **Total** | **518** | **100** | **590** | **+14** | **675** | **+30** |

**Source: National Energy Board, and Transport Canada; distributions within transport sector interpolated from Transport Canada estimates for 1987 and 2005.**

**a. One tonne of carbon dioxide contains 0.2727 tonnes of carbon.**
**b. Modal breakdown not available for 2010.**

The projections are made by the National Energy Board (NEB),[26] using historical relationships among $CO_2$, national output, population growth and energy prices. Central assumptions are that gross domestic product (GDP) will grow at 2.3% per annum, the number of households at about 1.4% per annum, and the car stock at about 1.5% per annum, while the price of crude oil increases from US$20/barrel in 1990 to US$27/barrel in 2010 (in constant 1990 dollars). Growth in energy use overall and in $CO_2$ are expected to be at lower rates over the next 20 years than during the last two decades, which will continue the substantial downward trend in emissions per unit of GDP.

The table shows that NEB's base-case forecast for 2000 is for total $CO_2$ to increase by 14% from 1990, to about 590 Mt. The overall growth predicted for transport sources to 2000 is about the same as for all other sources, but within transport the contributions of heavy trucks and aircraft increase faster than those of the other vehicle types.

By 2010, the base-case forecast is for emissions to increase by about 30% over 1990 levels to 675 Mt. The greatest increases are in industrial uses (50% over 1990 levels) and power generation and producer consumption (40%). Growth is expected to be only about 15% in the transport sector, and negligible in residential energy use.

## 4.2 CANADA'S GOALS ON GLOBAL WARMING

### 4.2.1 CFCs

With the protocol signed in 1987 in Montreal, Canada committed to a 50% reduction of CFCs by 2000. At the London Conference of June 1990, all original signatories agreed to increase the target to 100% phase-out by 2000, while Canada and 12 other countries declared they would eliminate CFCs by 1997. The prime motivation for CFC control is protection of the stratospheric ozone layer, but CFCs are also the most potent of the greenhouse gases per unit of weight.

### 4.2.2 $CO_2$

At the May 1990, UN Conference in Bergen, Norway, Canada committed to stabilize greenhouse gas emissions, other than CFCs, at 1990 levels by 2000. The CCME describes this as "a national target which does not pertain to specific regions or sectors." Canada is also committed to the UN Framework Convention on Climate Change, completed in May 1992, and signed by the Prime Minister at the UN Conference on Environment and Development in Rio de Janeiro in

June 1992.[27] That convention is less specific in its goals. Its objective reads in part (Article 2):

> The ultimate objective . . . is to achieve . . . stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner.

Its "commitments" in Article 4 include:

> Each of [the developed country] Parties shall adopt national policies and take corresponding measures on the mitigation of climate change, by limiting its anthropogenic emissions of greenhouse gases and protecting and enhancing its greenhouse gas sinks and reservoirs. These policies and measures will demonstrate that developed countries are taking the lead in modifying longer-term trends in anthropogenic emissions consistent with the objective of the Convention, recognizing that the return by the end of the present decade to earlier levels of anthropogenic emissions and other greenhouse gases . . . would contribute to such modification. . . .

and:

> In order to promote progress to this end, each of these Parties shall communicate, within six months of entry into force of the Convention for it and periodically thereafter, . . . detailed information on its policies and measures . . . as well as on its resulting projected anthropogenic emissions . . . with the aim or returning individually or jointly to their 1990 levels these anthropogenic emissions of carbon dioxide and other greenhouse gases. . . .

As illustrated by Table 7(2)-6, the goal of stabilization by 2000 at 1990 levels would require reductions in national $CO_2$ emissions by 14% from the NEB base-case forecast — in addition to the improvements in motor-vehicle fuel consumption and residential conservation already included in that forecast.

## 4.3 $CO_2$ REDUCTION MEASURES: TRANSPORTATION FUEL CONSERVATION

Federal fuel consumption policy has been limited to road vehicles, specifically cars, pick-up trucks and vans. In 1976, the government agreed with motor-vehicle manufacturers that the U.S. standards for fuel consumption of new vehicles would be met in Canada on a voluntary basis. These standards involve average fuel consumption targets being met separately for cars and "light trucks," averaged across each manufacturer's sales. With the agreements being renewed periodically, this has meant that Canada has essentially achieved fuel consumption improvements matching those under the U.S. mandatory standards. (In fact, Canadian fuel consumption has been slightly better in recent years, as Canadians have, on average, bought slightly lighter and smaller-engined vehicles than Americans.)

Extensive action has been taken by provincial and municipal governments to achieve greater fuel efficiency in transport. The 1970s and 1980s saw the introduction of a great variety of measures to encourage the use of public transport and discourage the use of private cars, including expansions of public transit networks and greater subsidization of their use; "park-and-ride" facilities; incentives for car-pooling; and traffic control and parking restrictions to limit use of private cars. In addition, incentives have been offered for using propane or compressed natural gas (conversion grants and lower excise taxes on the fuels), and many provinces and municipalities have converted some of their own vehicles to use these alternative fuels.

The federal government expects that substantial improvements in new motor-vehicle fuel consumption will continue to be made by manufacturers in the coming decades. *Canada's Green Plan*[28] includes reconsideration of mandatory federal standards. A radical tightening of U.S. fuel efficiency standards is also under consideration (to an average of 40 miles per U.S. gallon for cars). In Canadian terms, this equates to 5.9 L/100 km — compared with the current voluntary standard for new vehicles of 8.6 L/100 km, and the average consumption of cars in use of about 12 L/100 km. Such improvements are feasible through a combination of increased engine efficiency and reduction in vehicle weight.[29]

It can also be anticipated that development of alternative fuels for motor vehicles will help to limit the use of gasoline and diesel fuel. Of the alternatives available in the immediate future, compressed natural gas offers the potential of up to a 20% reduction in $CO_2$ per unit of distance (over the whole cycle of production and use), while methanol offers less than 5% if produced from natural gas, and up to 100% if produced from biomass.[30] Some experts suggest that, in the long term, a transport system fuelled by electricity (produced without carbon fuels, by using hydro-electric, nuclear or solar energy) or fuelled by hydrogen will develop.[31] Such fuels would emit almost none of the pollutants and greenhouse gases. However, the prospects of this system developing on a large scale within the next 30 years or so remain very remote,[32] and the carbon-fuelled internal combustion engine will likely survive with little change for at least that period. In the interim, air pollutant and $CO_2$ emissions should be reduced substantially as vehicle fuel consumption improves, and it is likely also that greater use will be made of such alternative fuels as methanol, propane and natural gas, offering further reductions.

## 4.4 POTENTIAL $CO_2$ REDUCTION MEASURES

CCME has announced some initial steps toward setting sectoral goals, but has not yet agreed on programs. Its *National Action Strategy on Global Warming* suggests specific measures that might be pursued, including:

- replacing the use of fossil fuel in generating electricity by using nuclear, hydro-electric, wind, solar or tidal power;

- obtaining more efficient generation from fossil fuels, for example, by using "clean coal" technology or cogeneration;
- investing in conservation rather than generating capacity;
- applying "marginal cost and peak-load pricing" of electricity;
- increasing the use of mass transit, through restricting car access to city cores, raising parking fees, or charging urban highway tolls;
- improving traffic flows and reducing traffic densities through urban signal coordination, and so on; and
- promoting staggered working hours and working at home.[33]

The U.S. National Academy of Sciences study also includes an assessment of potential mitigation technologies.[34] Its conclusion is that decisions should be guided by the overall cost-effectiveness of the options, and it recommends that a substantial list of currently available technologies be adopted. The study concludes that this action could reduce U.S. greenhouse gas emissions by 10% to 40%, at relatively low costs or even at net savings.[35] It further states that options requiring great expense are not justified. It recommends moving toward "full-cost pricing" of energy.

## 5. POTENTIAL ROLE OF ECONOMIC INSTRUMENTS

Recent discussions of strategies for environmental protection, in Canada and elsewhere, give great prominence to the potential of applying pricing or using other market mechanisms (referred to more generally as "economic instruments") instead of, or in support of, regulations.[36] As well as specific pricing proposals, the CCME Strategy on $CO_2$ emphasizes the potential role for more general economic instruments such as carbon taxes or a carbon emissions trading system.[37] The *Green Plan* frequently mentions the potential for economic instruments, and recommends their development.[38]

Also, under the $NO_x$/VOC Management Plan, consideration is being given to introducing emissions trading programs within one non-attainment area, the Lower Fraser Valley.[39]

The main economic instruments of relevance are emissions charges and tradeable emissions permits.

## 5.1 EMISSIONS CHARGES[40]

### 5.1.1 Description

The most elegant form of emissions charging system would add the social costs imposed by the emissions to the price of any activity that produced them.[41] Those activities would then only be undertaken if participants obtained benefits that outweighed the social costs, and participants would also invest in controls that were cheaper than the alternative charges. Economists predict that, unless the type of environmental damage is so severe that it must be entirely eradicated, charging for its costs would be more efficient than regulating its reduction because charging would automatically lead to the least-cost pattern of abatement. To achieve the same result through regulation, the regulator would need to differentiate regulated limits for each class of polluters on the basis of the relative costs for pollution reduction. This would be complex, and regulators are unlikely to have the required information.

Furthermore, the social costs of damage could be incorporated into "benefit-cost" analyses of proposed system investments, to give appropriate weight to environmental concerns in comparisons of investments among modes (and between transport and other activities).

Thus, the simple prescription for achieving an efficient level of damage mitigation is to identify the costs imposed by the environmental damage that are attributable to each mode, and to incorporate them in user-charges.

### 5.1.2 Can Damage Costs be Estimated?

Many would counter that it is not possible to estimate costs for many aspects of damage, as does Environment Canada in its discussion paper on economic instruments.[42] The difficulties of determining costs have defeated most attempts to date, beyond some simple valuations of damages to materials or crops, when the damage is unequivocal and a market price can be referred to for its value. Two problems, respectively of science and economics, have proven intractable:

- identifying the damage caused by a unit of transport (passenger-kilometres/trip/mode); for example, by determining the extent to which people, plants and animals are harmed by transport emissions, noise or community disruption; and
- attributing money values to the damage.

It seems likely that scientific techniques will improve, though the medium-term prospects for improvements are limited, especially for quantification of the health effects. Some economists believe that there has been great progress recently in attributing money values for damage through such techniques as asking individuals what they would pay in hypothetical trading situations for improvements in environmental conditions.[43] When structured carefully, these experiments are impressive, and a growing body of social scientists finds them credible. While it might be credible, however, to use resulting values in cost-benefit analyses of control measures (in which analytical techniques can overcome experimental uncertainty), the hypothetical nature of these values would pose very substantial problems of public credibility if attempts were made to base prices on them.

It is also possible in some cases to estimate the costs of cleaning up environmental damage, which might provide a proxy for the social cost of the damage itself, and a basis for charging the polluters. In Europe, some public agencies charge companies for the treatment costs of chemical discharges into waterways.[44] It has been suggested that the principle might be applicable to global warming damage, estimating the costs to mitigate flood damage from rising sea levels, for example (and possibly basing charges for $CO_2$ emissions on them). The principle, however, is by no means applicable to all types of environmental damage, as some types are completely irreversible (for example, the loss of a species), while for others, including air pollution, there are no clean-up options.

Problems of valuing noise damage are arguably less difficult than those for air pollution, because the sources and effects are easier to measure — particularly in the case of aircraft noise — and also because individual behaviour to avoid or accommodate noise is easier to measure. Nevertheless, considerable ingenuity is still required to infer values for noise, for example, from the effects of noise on house prices.[45]

### 5.1.3 Alternative Bases for Setting Emissions Charges

*Costs to achieve pollution reduction targets:* When national or international targets for pollution reduction are accepted, predictions of average reactions of transport users to changes in prices may indicate the level of emission charge that needs to be imposed to reach the goal. For example, it should be possible to examine the national $NO_x$ goal and to infer the emissions surcharge on gasoline that would be needed to achieve the required reduction in that sector. It should also be possible to extend the analysis to consider what combinations of surcharges on the various fuels or engines might be needed throughout the transportation sector, and to do the same for all other sectors, in order to design a broad strategy.

While such an inferential procedure does not directly use the information available on the extent and value of environmental damage, this information will likely be assessed by policy makers in setting the national goals. The charges inferred to meet the goals would then also be based implicitly on that information.

Such inference of charges required to meet goals is the focus of much recent discussion of carbon taxes. Predictions of the reactions of industry and the public to such taxes in the United States have suggested that carbon taxes might need to be between about US$100/t and US$400/t of carbon to reach the Toronto Conference goal of 20% reduction in $CO_2$ by 2005.[46] Similar modelling in Canada has suggested that achieving the extra 15% reduction in $CO_2$ needed to meet the national stabilization goal in 2000 would necessitate a tax of about $120/t of carbon. This would amount to 7.7¢/L of gasoline, and 9¢/L of diesel fuel.

The appropriate goal for $CO_2$ reduction remains the subject of great debate, and of international negotiations.[47] Some economists reject the proposals for carbon taxing on the scale required to stabilize $CO_2$ emissions at 1990 levels, or to meet the Toronto Conference goal of a 20% reduction, arguing that it is not necessary at present to adopt an arbitrary goal that is expensive to meet. The U.S. studies mentioned earlier suggest that the annual costs of achieving the Toronto goal through carbon taxing would range from about 1% to 3% of gross national product. It can be argued that efforts might, at present, be better directed at defining more clearly the nature of the effects of global warming, and therefore the magnitude of the benefits to be gained from its control, and also at developing means to reduce emissions more cheaply in future.[48] Proponents of this view suggest that a modest carbon tax be introduced in the interim in order to steer behaviour toward conservation and substitution of energy use.

Resolving these differing judgements of the appropriate levels of charges requires enhanced understanding of the nature and costs of global warming, further objective analysis of the cost-effectiveness of control options, and careful modelling of producers' and consumers' reactions to charges in all relevant sectors of the economy.

*Costs of damage implicit in previous regulatory decisions:* Adoption by government of environmental damage regulations involves either explicit or implicit acceptance of its cost-effectiveness, in costs per unit of damage prevented. It can be inferred that the government believes the cost of the regulation per unit of damage prevented to be somewhat less than the social costs the damage would impose (otherwise they would prefer the damage). By extension, it could be argued that the implied unit cost of the regulation provides a minimum social cost to be used as a basis for setting charges for remaining emissions. This has been the argument used in Sweden, where a parliamentary agency endorsed the use as emissions charges of values per unit of emissions implicit in a previous decision to impose a motor-vehicle equipment regulation.[49]

An analogous inference could be made in Canada from the 1987 motor-vehicle emission standards, for example, that the cost per tonne of $NO_x$ reduction was about $2,000.[50] If this is a reasonable charge for remaining $NO_x$ emissions, it would imply a surcharge of about 0.12 cents per kilometre for cars, or 1 cent per litre of gasoline, and 0.74 cents per kilometre for heavy trucks, or about 1.2 cents per litre of diesel. Such charges should, of course, be extended logically beyond the transport sector.

## 5.2. TRADEABLE EMISSIONS PERMITS

### 5.2.1 Description[51]

The essence of a permit system is that the total amount of allowable emissions is determined in advance by the regulatory agency. Permits are then issued (donated or sold) only up to that limit, and they can be traded among emitters of pollution. The system is intended to introduce some flexibility compared with the customary regulatory procedure in which the emissions of every company are specified by the regulator. Under the permit system, if there are substantial differences in costs of meeting the standards among companies, one with high costs can effectively choose to pay a low-cost company to reduce emissions instead, by the device of buying the latter's permits. If the high-cost company pays a price for the permits lower than its own costs of abatement but higher than those of the low-cost company, both companies are better off by the trade, as is the economy as a whole. The regulator's goal of the specified emissions limit is achieved, but at a lower cost than if the companies were required to abate equally.

If each company faces the same cost structure, there will be no trades, and if there are substantial costs in organizing trades, they might wipe out the potential gains. Alternatively, the scheme might be frustrated by low-cost firms refusing to trade, in order to gain a competitive advantage, or by high-cost firms choosing not to buy permits, to avoid public censure. In any of these cases, a permit scheme reverts to being a customary regulation. Therefore, permit schemes will, at worst, impose the same costs as regulations, and offer the prospect of achieving emissions reductions more cost-effectively.

### 5.2.2 Potential Relevance of Tradeable Permits to Transportation Emissions

No workable system of tradeable permits for individual transport vehicles has been designed. The flexibility of vehicle use, and therefore the unpredictability of their emissions in any specified time period, makes it difficult to envisage a permit system that is not also an administrative nightmare. For example, consider the case of $NO_x$ emissions, which arise from many different types of processes, with major differences in the costs of abatement (for example, between pulp mills, power plants, passenger cars and diesel trucks). Cost-effectiveness comparisons show it could be cheaper for car drivers to pay for $NO_x$ reductions in pulp mills than to obtain the equivalent reduction by buying Californian engine controls (or being forced to do so by a regulation).[52] But to address this with a permit system would require issuing and then monitoring trades in large numbers of permits for the very small amounts individuals would need (for example, an estimated vehicle-year's emissions or a vehicle-lifetime's emissions).

Alternatively, permits could be issued to vehicle manufacturers for their whole production fleet, allowing them to trade with other sources.[53] This would require manufacturers to take responsibility for the lifetime use of vehicles, so the requirements for monitoring by the regulatory agency (or the manufacturers) would still be stringent.

There would seem to be greater potential to design trading schemes that involved rail or air carriers, with fewer participants, and more predictable and monitorable emissions, but the payoff would not be great due to the relatively small total contributions of these modes to total emissions.

Some less ambitious variants of tradeable permits might be more feasible, and preferable to simple customary regulation in allowing more flexibility and lower compliance costs. An example might be to allow trading at least within an individual company. Rather than setting targets for each unit of production, a company-wide target would be set, and the company could meet the target however it pleased. Such corporate targets are the chosen means of regulating motor-vehicle fuel consumption, where the manufacturer meets a sales-weighted average consumption across all models, but, conspicuously, not for motor-vehicle emissions standards, in which each model must meet the same standard (in grams per kilometre). The government could obtain the same aggregate performance from each manufacturer with a corporate average emission rate, while allowing manufacturers the flexibility to achieve this at lowest cost by focussing on models in which abatement is cheaper (avoiding expensive re-design of old models, for example). Furthermore, if the target is expressed this way as an average emission rate (rather than total emissions from the vehicles concerned, with all the attendant problems of controlling vehicles over their lifetime), it becomes more reasonable to consider trading of those emissions rights among manufacturers. Companies producing predominantly cleaner (smaller) cars would sell their rights to those producing more-polluting (larger) ones.

## 5.3 EQUITY ISSUES IN ECONOMIC INSTRUMENTS

Environmental damage from transportation is arguably largely unfair, in that those harmed are usually not responsible, and are usually not compensated for damage. Furthermore, to the extent that regulations are inefficient through requiring the same emissions reduction (and its costs) to be borne by all, when the effects differ by location, those who do not travel in sensitive areas are unfairly penalized. Emissions charges that forced polluters to pay, and were differentiated by amounts of damage, would be fairer.

Emission charges, however, that were consistent across the modes — the same for each unit of pollutant — might pose some thorny equity questions. Current evidence suggests emissions are higher per passenger-kilometre by train than by car (discussed later in this chapter); therefore, charges per passenger would be higher for rail passengers than car passengers. It would be argued that such charges were regressive. Also, of course, the higher emissions for trains reflect current equipment and load factors, which rail passengers would be quick to claim were beyond their responsibility.

The equity implications of extending emissions charges to urban transportation would also be important. Charging car users for their emissions, through surcharges on gasoline taxes or registration fees, would be characterized as tax hikes, and viewed with suspicion because of their possibly regressive effects. In the case of poorer residents of our largest cities, if they were forced by circumstance to drive older, more-polluting cars, they would face surcharges higher than those in the surrounding areas, and higher than the average, and yet they would also be subject to the worst of the city environment themselves.

Similarly, introducing a carbon tax for $CO_2$ control would raise the question of its incidence by income group, and also by province or region, as its implications for electricity pricing became clear.

Finally, the emissions permit trading systems would have some equity implications, in apparently allowing permit buyers to meet lower pollution limits than permit sellers. (In other words, vehicle manufacturers might buy permits rather than reduce emissions in larger vehicles or older designs.) This might be perceived as unfair (though a strong counter-argument would be that such permit buyers are meeting the same standards, but choosing to do so by paying for emission reduction to be gained more cheaply elsewhere).

### 5.3.1 Uses of Revenues from Charges/Permits

As the charges would be payments for the social costs of environmental damage, Chapter 7 of Volume 1 of this report recommends that they should be paid to the government(s), rather than to the owners of the infrastructure (if separate agencies), and should not be used for system development. Charges might be used to pay for cleaning up the damage, in the limited cases where that is possible, or for compensating victims of damage, in the cases where they might be identifiable (which seems remote in the case of most air pollutants or for global warming). The remainder would probably constitute large amounts of new revenue to governments. There seems no compelling argument for earmarking these revenues for general use in environmental programs outside transport (as some environmental advocates have proposed).

## 6. Illustrations of the Possible Costs of Damage from Emissions and of the Potential Magnitude of Emissions Charges

Attempts are made later to illustrate the possible magnitude of costs of damage for each of the intercity passenger modes on a comparable basis. The system-wide averages per passenger-kilometre are provided, as are totals for two sample trips. It is supposed that the estimated damage costs could provide a basis for setting charges by mode.

The detailed design of environmental charges would be a complex effort, because the transfers of money involved on a national scale are potentially very large. The Royal Commission has not attempted the task, because the effects of possible charges on all damage sources would need to be predicted and judged, and these sources extend considerably beyond the transportation sector. This task should be undertaken by the departments of federal, provincial and territorial governments responsible for transport, environment, energy and finance.

All sources of environmental damage should be considered, possibly including disruption of social activities and other forms of "disamenity" experienced by those in proximity to transport facilities, as well as the more obvious forms of discharges and pollution. For the present, some hypothetical possibilities of charges are offered here based only on the damage from emissions of $CO_2$, $NO_x$ and VOCs, together with aircraft noise, to illustrate the potential magnitude of surcharges, and how they might differ by mode. These are obviously not the only sources of environmental damage, but are possibly the most important, and are also those on which some scant information on possible costs is available.

Other components of emissions have been purposefully ignored. Carbon monoxide and particulate emissions are assumed irrelevant for intercity trips, as their damage is essentially urban, and $SO_2$ emissions from transportation are assumed to be so small a proportion of total national $SO_2$ emissions as to be negligible. These assumptions might prove incorrect when detailed design of potential charges was undertaken.

## 6.1 AVERAGE COSTS OF ENVIRONMENTAL DAMAGE FROM AIR POLLUTANTS AND $CO_2$ BY MODE

There are no convincing estimates of the average costs of environmental damage from $CO_2$, $NO_x$ and VOCs. In preparing the Royal Commission's estimates of comprehensive costs by mode, it has therefore been assumed that the charges necessary to achieve nationally declared goals for these emissions reflect the social value placed on preventing the damage. For $CO_2$, reviews were made of estimates in the United States and Canada of the prices that would be necessary to stabilize total $CO_2$ emissions from all sources at 1990 levels in 2000. In Canada, modelling has suggested that the necessary price is about $120/t of carbon, which is equivalent to $32.70/t of $CO_2$, or 3.27¢/kg (in 1991 dollars). This is used here as an estimate of the environmental damage from $CO_2$.

For $NO_x$ and VOCs, no similar modelling appears to have been undertaken of the charges that might be sufficient to meet Canada's announced goals. At present, therefore, the charges can only be guessed to illustrate the costs and potential charges if the Royal Commission's recommendations are implemented. The task of making reliable estimates (or estimating damage losses from these emissions in some other manner) would be an initial priority in implementing the proposals.

The guesswork is guided by the $NO_x$/VOCs Management Plan, which produced some (very rough) estimates of the cost-effectiveness of a number of its proposed policies, in cost per tonne of emission prevented.[54] Measures considered acceptable in the Plan — various technological controls and limitations on activities — have an upper limit of cost of about $3,000 per tonne of either emission prevented (in 1989 prices). These measures in total are not sufficient to achieve Canada's recently announced goals for $NO_x$ and VOCs reductions, so it can be deduced that to succeed in achieving them would require measures costing more than $3,000 per tonne. An initial guess is that such measures might cost $5,000 per tonne (in 1991 prices). (It is noted that measures are under consideration in the United States that would cost several times this amount per tonne of VOCs prevented.)[55] Then it can be suggested that the goals could alternatively be achieved through setting a price of that same amount of $5,000 per tonne, from rough reasoning that such a price would induce manufacturers and consumers to take advantage of all possible control measures and behavioural changes that cost less than $5,000 per tonne. In support of these prices, it should be noted that the prices introduced in Sweden for $NO_x$ and VOCs emissions amount apparently to about US$7,150 per tonne of $NO_x$ and about US$3,550 per tonne of VOCs.[56]

Whether the prices for $NO_x$ and VOCs should be equal in Canada should also be addressed in implementing the Royal Commission's proposals. For the present, it should be noted that the question of the relative contributions of the two types of emissions to low-level ozone formation in Canada's ozone-sensitive regions has not been definitively answered, though the $NO_x$/VOCs Management Plan suggests pursuing both $NO_x$ and VOCs reductions with equal urgency. The Plan also implicitly endorses an equal value for damage in proposing the adoption of measures with the same upper limit on cost-effectiveness per tonne. For illustrative purposes, the value of $5,000 per tonne ($5 per kilogram) is used in the Royal Commission's costing for both $NO_x$ and VOCs.

It must also be decided whether the damage costs and any prices that emerge from these costings apply equally throughout Canada. It is clear from Environment Canada and CCME decisions that the effects of low-level ozone are considered much worse within the three ozone-sensitive regions now designated as requiring special attention — the Lower Fraser Valley, Windsor to Quebec City corridor and southeastern New Brunswick. It is assumed for illustrative purposes that the costs of damage arise from emissions of $NO_x$ and VOCs only in those regions. Estimates must therefore be made of the proportions of total emissions by mode that arise within the sensitive regions. From the Canadian Travel Survey for 1988, it was reported that about 70% of the car-kilometres in long-distance trips were driven within the provinces of British Columbia, Ontario, Quebec and New Brunswick. It is guessed that the proportion of that travel, and its fuel and emissions, within the ozone-sensitive regions was around 70%, so about 50% (70% of 70%) of national intercity car traffic was within those regions. The damage cost of $5,000 per tonne of $NO_x$ and VOCs is therefore applied to 50% of the average national emissions by car per passenger-kilometre. Similarly, the proportions of bus and train fuel use and emissions within the sensitive regions are guessed to also be 50%, while that of aviation emissions is guessed at 20%. (The average $NO_x$ and VOCs emissions from aircraft are low relative to the other modes and also relative to aircraft $CO_2$ emissions, so the margin of error in the final estimate of the damage costs for aircraft is relatively unimportant.) For ferries, it is assumed that none of the emissions are within the sensitive regions (which ignores ferry contributions to problems in southern British Columbia and around Saint John, New Brunswick).

Furthermore, the focus must be on those periods when the emissions are most damaging. Concentrations of ozone exceeding the maximum acceptable NAAQO occur primarily in the summer months, in episodes lasting a few hours or days. It is assumed that charging \$5,000 per tonne for $NO_x$ and VOCs only during the summer season would prompt adoption of measures that achieve the goals. Costs are therefore counted only for the emissions in that season. Monthly counts from the Canadian observation stations of episodes in which ozone exceeds the maximum acceptable NAAQO show that they are concentrated in the months of May to August.[57] The target season for ozone charges is therefore defined as May to August. Within those four months, it is assumed (based roughly on fuel sales by month) that emissions in each mode account for 40% of the annual total.

Finally, applying the above values of \$32.70 per tonne of $CO_2$, and \$5,000 per tonne of $NO_x$ or VOCs within the ozone-sensitive regions, to 40% (summertime proportion) of the emissions per passenger-kilometre by mode in Table 7(2)-3, the following system-wide average costs of emissions per passenger-kilometre by mode are obtained (and used in the system-wide average costing in Volume 1, Chapter 3 of this report).

*Table 7(2)-7*

*Estimated Costs of System-Wide, Year-Round Emissions per Passenger-Kilometre (1991 cents per passenger-kilometre)*

| Mode | $CO_2$ | $NO_x$/VOCs | Combined |
|---|---|---|---|
| Bus | 0.169 | 0.077 | 0.246 |
| Car | 0.410 | 0.166 | 0.577 |
| Train | 0.382 | 0.259 | 0.642 |
| Airplane | 0.899 | 0.022 | 0.921 |
| Ferry | 1.972 | 0.000 | 1.972 |

## 6.2 ILLUSTRATION OF POTENTIAL MAGNITUDE OF EMISSIONS CHARGES FOR SAMPLE ROUTES

The examples used in Volume 1, Chapter 7 are for the trips from Toronto to Montreal and Saskatoon to Halifax. To estimate the environmental damage, the first step is to estimate the amounts of emissions by mode for each of the trips. The emissions per unit of fuel energy used in each mode are expected to remain as shown in Table 7(2)-1, but the emissions per passenger-kilometre are expected to differ from the system-wide averages shown in Table 7(2)-3 because equipment and load factors vary by route for the public modes, and so, therefore, do the amounts of fuel used per passenger-kilometre. Royal Commission staff estimates of the amount of fuel required per passenger-trip (consistent with the vehicle/carrier costing elsewhere in this report) are shown in Table 7(2)-8.

*Table 7(2)-8*

*Fuel Use per Passenger-Trip by Mode, for Sample Routes (litres/passenger-trip)*

| Mode | Toronto to Montreal | Saskatoon to Halifax |
|---|---|---|
| Bus | 5.9 | 67 |
| Car | 28.9 | 240 |
| Train | 15.0 | 283 |
| Airplane | 40.8 | 219 |

Multiplying the energy used in megajoules per passenger-kilometre (using values from Table 7(2)-2) by the ratios of emissions to energy use by mode (in Table 7(2)-1) provides measures of the emissions of $CO_2$, $NO_x$ and VOCs per passenger-kilometre. These values are shown in Table 7(2)-9, for the two sample routes. (This table appears in a slightly different form in Chapter 7 of Volume 1 as Table 7-1.)

*Table 7(2)-9*
*EMISSIONS PER PASSENGER-KILOMETRE (GRAMS)*

| **Toronto to Montreal** | | | | | | | |
|---|---|---|---|---|---|---|---|
| | | | | | **If all seats filled** | | |

**Sources: Emissions per unit fuel from VHB Research & Consulting, "Environmental Damage from Transportation." Fuel consumption per pass-km estimated by Royal Commission staff.**

As noted, the emissions rates depend on the assumed load factors of the public modes, shown for each route in the final row of Table 7(2)-9. To show the importance of the load factors, the table also shows the potential emissions per passenger-kilometre if all seats were filled. No load factor for cars is shown, but the assumed car occupancy of about 1.8 implies a load factor of only 35%. Filling all car seats could then potentially reduce car emissions per passenger-kilometre by about 65%.

To estimate the damage costs, and potential emissions charges to recuperate them, the total emissions per passenger-trip are estimated, as shown in Table 7(2)-10. The table indicates the trip distances by mode, and total emissions of $CO_2$, $NO_x$ and VOCs per passenger-trip. However, as discussed, the emissions of the ozone precursors, $NO_x$ and VOCs, are assumed to produce damage only when released in the ozone non-attainment areas. The table therefore indicates the distance by each mode that is assumed to take place within such areas. For the Toronto to Montreal trip, all of the surface routes are within the Windsor to Quebec City corridor, while for the Saskatoon to Halifax trip, only those parts of the trip within that ozone non-attainment area and the one in southeastern New Brunswick are included.

**Sources: Emissions per unit fuel from VHB Research & Consulting, "Environmental Damage from Transportation." Fuel consumption per pass-km and route distances estimated by Royal Commission staff.**

For the airplane trips, it is assumed that the emissions at cruising height are too high to contribute to low-level ozone concentrations. An estimate of the emissions that do contribute to low-level ozone is obtained using the constant term from the fuel consumption equation used in the air carrier costing model. Approximately 35 L per aircraft trip is constant over a trip of any distance, contributing to low-level ozone through climbing, descending, taxiing and idling. The figures in Table 7(2)-10 for airplane-trip "kilometres in ozone-sensitive zones" are obtained by expressing 35 L as a proportion of total fuel used per passenger-trip, and multiplying this by total trip distance.

The illustrative emissions charges are then obtained by multiplying the $CO_2$ emissions in Table 7(2)-10 by 3.27¢/kg, and the $NO_x$ and VOCs emissions in the sensitive regions by $5/kg. The results are shown in Table 7(2)-11, which appears (with rounded values) as Tables 7-2 and 7-3 in Volume 1, Chapter 7.

## 6.3 ESTIMATES OF ENERGY USE AND EMISSIONS BY HIGH-SPEED RAIL

The estimates of possible emission charges for high-speed trains in Volume 1, Chapter 7 of the report are based on the following analysis.

### 6.3.1 Energy Use

Estimates of the energy requirement for a service like the "train à grande vitesse" (TGV), operating in the Windsor to Quebec City corridor (at 300 km/h), are available as follows:

The power required from the electricity grid into the rail system is estimated by Lake et al. as:[58]

- 0.083 kilowatt-hours (kWh) per passenger-kilometre,
- where 1.0 kWh equals 3.6 MJ.

In other words, the service would require 300 kJ of energy per passenger-kilometre.[59]

Khan's report[60] quotes Johnson et al.[61] for an estimate of the power required from the electricity grid as:

- 275 kJ/seat-kilometre.

The estimated average train occupancy on the proposed Toronto to Montreal route is:

- 75%.

This means that:

- 370 kJ of energy per passenger-kilometre would be used.

Khan also considers the source of the electricity. He estimates that the combined electricity output of Ontario and Quebec is provided approximately 55% by hydro-electricity plants and 45% by thermal (including nuclear) plants. He suggests that of the "primary" fuel used for the thermal plants, 3.6% is required to process and transport the fuel to generating plants, and up to 70% is lost in the generation process. For either thermal or hydro-electricity, he suggests 15% of power supplied by the plants is lost in transmission and delivery within the rail system. In sum, he estimates that, on average in the two provinces, only 55% of "primary" energy (electricity from the hydro plants, or initial fuel for thermal plants) reaches the trains. Therefore he suggests that the 275 kJ/seat-kilometre in "secondary" energy requires (275/0.55 =) 500 kJ/seat-kilometre in "primary" energy. Using his 75% average train occupancy, this equals an energy requirement of 670 kJ/per passenger-kilometre.

The report of the Ontario/Quebec Rapid Train Task Force[62] quotes estimates made by Ontario's Ministry of Transportation of "overall energy efficiency" of current modes and future options for high-speed rail and magnetic levitation (maglev) trains, including the following kilowatt-hours per passenger-kilometre for the 300 km/h TGV Atlantique or ICE in a Windsor to Quebec City corridor service.[63] The final column converts these to kilojoules per passenger-kilometre.

| | kWh/pass-km | kJ/pass-km |
|---|---|---|
| Windsor to Toronto | 0.10–0.12 | 360–430 |
| Toronto to Montreal | 0.09–0.11 | 320–400 |
| Montreal to Quebec City | 0.11–0.13 | 400–470 |

It is not clear whether these estimates refer to "secondary" or "primary" power requirements, but it seems likely they are the power requirements of the rail system from the electricity grid.

### 6.3.2 Synthesis

These estimates lie in the range of 300 to 470 kJ/pass-km for all of the corridor services. For the Toronto to Montreal route, the estimates are 300 kJ/passenger-kilometre from Lake et al., 370 kJ/pass-km from Khan, and the range of 320 to 400 kJ/pass-km from the Ontario/ Quebec Rapid Train Task Force. An approximate mean of this range, for the purpose of showing the possible magnitudes of energy and emissions from high-speed trains relative to current modes, is 350 kJ/passenger-kilometre.

To the extent that the electricity was provided from fossil-fuel-fired plants, a conversion from "secondary" energy requirements to "primary" requirements is necessary, along the lines suggested by Khan. Khan's estimates of the average losses of energy in generation, however, are probably too pessimistic in their assumption that about 75% of Ontario's power comes from thermal stations with average conversion efficiency of 30%. For the present main purpose of comparing emissions from high-speed trains with those from other modes, the prime interest is in the amount of fossil fuel that might be used to generate the electricity. The conversion efficiency is only of relevance to the extent that the high-speed rail system would be supplied from fossil-fuel-fired plants. The current contribution of such plants in Ontario and Quebec is shown in Table 7(2)-12.

*Table 7(2)-12*

*SOURCES OF ELECTRIC POWER GENERATION IN ONTARIO AND QUEBEC, 1991*

| | Ontario | | Quebec | |
|---|---|---|---|---|
| **Source** | (GWh) | (%) | (GWh) | (%) |
| Hydro | 37,441 | 26.6 | 137,867 | 97.1 |
| Conventional steam | 31,483 | 22.4 | 264 | 0.2 |
| Nuclear | 70,773 | 50.3 | 3,910 | 2.7 |
| Other | 1,001 | 0.7 | (negligible) | |
| **Total** | **140,698** | **100.0** | **142,041** | **100.0** |

**Source: Statistics Canada, Catalogue No. 57-001.**

The "conventional steam" plants and the "other" plants in Ontario are fired by fossil fuels. Of the combined total for the two provinces, therefore, these provided some 11.6% of electricity generated in 1991. This proportion can be expected to decrease in the future, if plans are implemented in Quebec to increase its hydro-electric output and in Ontario to increase its nuclear output.[64]

The extent to which a high-speed rail system would in practice draw on the fossil-fuel-fired plants would depend on the production conditions at the time its demands were made. For certain trains at peak electricity demand times, it is possible that all of the marginal power used would be generated by the fossil-fuel-fired plants, while for others at off-peak times the marginal power would come entirely from hydro-electric or nuclear plants. For a simple illustration of the potential emissions, no attempt is made to predict the exact outcome, but the simple assumption is made that a high-speed rail system at the end of the current decade would draw from the electricity grids of Ontario and Quebec in an average manner. It could then be expected to receive about 10% of its electricity from fossil fuels. Recognizing that losses in generation in fossil-fuel-fired plants amount to 50% to 70% of total energy input, the "primary" fuel requirement to those generation stations can be estimated conservatively to be of the order of double the above rate per passenger-kilometre, or about 700 kJ/pass-km. The illustrations of potential emissions from high-speed rail that follow use these average assumptions: 10% of the electricity required for the trains is generated using fossil fuels, at an average energy intensity of 700 kJ/pass-km.[65]

### 6.3.3 Emissions

For comparisons with the environmental costs of other modes, all of the environmental impacts expected from each should be strictly accounted for. Due to the uncertainties of damage cost estimation, the cost analyses by mode are limited to those effects expected to be of most importance from intercity passenger transportation: the emissions of $CO_2$, $NO_x$ and VOCs. When considering the case of high-speed rail, only costs for emissions of $CO_2$ and air pollutants are shown, so only the fossil-fuel-fired portion of the electricity used is relevant. No costs are added for the other potentially important categories of environmental effects from hydro-electricity plants and nuclear generating stations.

The emissions of interest and importance from fossil-fuel-fired plants are $CO_2$, $NO_x$ and also $SO_2$. Sulphur dioxide is important because it damages health by aggravating respiratory complaints such as asthma and bronchitis, and because of its major contribution to acid rain. While $SO_2$ is produced in all combustion processes, the amounts created from fuel use by current intercity passenger transportation are considered sufficiently small, and their emissions sufficiently remote from sensitive populations, that no cost was assigned to them in the cost analyses in the earlier sections. However, the $SO_2$ from fossil-fuel-fired electricity plants is of sufficient importance that an attempt should be made to assign a cost to it, as has been done with $NO_x$ and VOCs.

Table 7(2)-13 shows the main components of the cost analysis:

Column 1 illustrates the emissions per unit of energy used in these plants:

- Emissions of $CO_2$ can be estimated from the carbon content of coal (assuming Canadian bituminous coal is used in power plants) as 92.1 g/MJ.[66]
- Emissions of $NO_x$ and $SO_2$ can be estimated from average rates forecast by Ontario Hydro for 1996 to 2000,[67] of 1.612 g/kWh of $NO_x$, and 4.0 g/kWh of $SO_2$. These convert to 0.448 g/MJ of $NO_x$ and 1.11 g/MJ of $SO_2$.

Column 2 shows the estimated energy requirement from fossil-fuel-fired plants of 700 kJ per passenger-kilometre.

Column 3 lists the grams of emissions per passenger-kilometre, which is the product of the previous two columns.

Column 4 shows the estimated costs per tonne of emissions. The amounts for $CO_2$ and $NO_x$ are as used throughout this environmental cost analysis, from amounts assumed to be necessary to meet national goals, of $120 per tonne carbon, or $32.70 per tonne $CO_2$, and $5,000 per tonne $NO_x$, when emitted in summer. The estimated cost of $SO_2$ is obtained from the report by VHB for the Royal Commission,[68] derived in turn from a review of cost estimates by Ottinger et al.[69] The cost is quoted as $5.29/kg in 1989 prices, which is inflated to 1991 prices, and converted to an estimate of $6,000 per tonne.

Column 5 estimates the costs in cents per passenger-kilometre, obtained as the product of columns 3 and 4.

*Table 7(2)-13*

*COSTS OF EMISSIONS FROM FOSSIL-FUEL-FIRED ELECTRICITY PLANTS, FOR HIGH-SPEED RAIL (1991 PRICES)*

| | g/MJ | kJ/pass-km | g/pass-km | | Cost ($/tonne) | Cost (¢/pass-km) |
|---|---|---|---|---|---|---|
| $CO_2$ | 92.10 | 700 | 64.50 | | 33 | 0.21 |
| $NO_x$ | 0.45 | 700 | 0.31 | summer | 5,000 | 0.16 |
| | | | | other seasons | 0 | 0.00 |
| $SO_2$ | 1.11 | 700 | 0.78 | | 6,000 | 0.47 |
| **Total** | | | | | **summer** | **0.84** |
| | | | | | **other seasons** | **0.68** |
| | | | | | **average** | **0.74**[a] |

**a. Assuming summer emissions are 40% of the annual total.**

The emissions costs are thus estimated to range between zero, when the electricity is generated from non-fossil sources, to about 0.73 cents per passenger-kilometre when the electricity is entirely from fossil fuel. Then it remains to estimate average costs per passenger-kilometre for electricity used in high-speed rail, given the proportion of the power to be provided by fossil-fuel-fired plants. As noted earlier, the assumption is made that this proportion will, on average, be the same as the contribution of fossil-fuel-fired plants to total electricity generated in Ontario and Quebec: about 10%. The final estimated costs of the emissions from high-speed rail are therefore approximately

(10% of 0.84¢ =) 0.08¢/pass-km in summer, and 0.07¢/pass-km in the rest of the year. A rounded estimate of the year-round average, with about 40% of fuel use in summer, would be 0.07¢/pass-km.

## 6.4 ESTIMATES OF AIRCRAFT NOISE COSTS

Costs for aircraft noise are included in the system-wide costs and costs for sample routes in Chapters 3 and 18 of Volume 1 of this report, based on the following information.

Estimates of the costs of noise at Toronto and Vancouver airports are obtained from Gillen and Levesque.[70] The authors infer values of noise nuisance from those airports, and estimate noise costs for various models of aircraft. Their findings imply that there are substantially greater costs for "Stage 2" aircraft than for those with "Stage 3" noise controls. For example, the cost per movement for a B767-200 is $89 at Lester B. Pearson International Airport in Toronto compared with $123 for a B737-200 and $138 for a DC9-30. The costs are somewhat different at Vancouver from those at Pearson, and no simple averages for all types of aircraft are presented. For purposes of illustration, however, only orders of magnitude are necessary, and it is apparent from the tables that the cost per seat-movement is somewhat above $1.00 for the older aircraft, and below $0.50 for the newer models. Taking average occupancies into account, it will be assumed that it is reasonable to represent noise costs at these two airports as $1.00 per person-movement, in round figures (a figure somewhat higher than the source tables would suggest).

Then it is assumed that similar noise costs hold at Montreal's Dorval Airport, but that noise costs are otherwise negligible at Canadian airports. (This is not realistic but possibly counters the overstatement of costs at the main airports.) These three major airports account for 60% of total enplaned/deplaned passengers in Canada (including international passengers). It is therefore assumed that noise costs are, in very rounded figures, closer to $0.50 per passenger-movement nation-wide, or $1.00 per passenger-trip. This cost is included in the estimates of system-average environmental damage costs in Volume 1, Chapter 3 of this report, and for the costs of the sample routes, the costs are assumed to occur only at the major three airports, as $1.00 per passenger-movement.

Barrett, *Aircraft Pollution, Environmental Impacts and Future Solutions,* World Wildlife Fund, Aug. 1991.

6. VHB Research & Consulting, "Environmental Damage," Table 4.

7. The estimate of pass-km per litre for ferries might be underestimated as fuel use is allocated between passenger and freight traffic according to deck space used, with no allowance for any effect of vehicle loads on fuel consumption. If weight were the only determinant, passengers and their vehicles would be responsible for much less fuel use, and the estimate of pass-km per litre in the table might rise by 50% or so. Information on vehicle loads is not available, but it is believed that they are of only minor additional importance to fuel consumption once use of deck space is allowed for.

**ENDNOTES** 286

# INTRODUCTION

The issues of transport safety were considered by the research staff of the Royal Commission, rather than through contracted research. The following notes are therefore more detailed than those supported by reports from contracted research.

## 1. SUMMARY OF TRANSPORT SAFETY

The history of transport safety shows that deaths, injuries and property damage have increased as traffic has grown. For example, there were 521 deaths in rail and road transport in 1921 and 4,060 deaths in 1990, while injuries and property damage increased faster still. The increase in accidents and casualties[1] over the long term, however, has been much less than the increase in traffic. The number of road fatalities grew quickly in the early days of motorization, but since 1930 it has only tripled, while the number of vehicles has increased 14-fold. It can be concluded that the "risks"[2] of accidents and casualties per vehicle-kilometre and per passenger-kilometre (pass-km) have fallen substantially. Recently, the improvement has been even more impressive. Since 1973, risks of death and serious injury have fallen faster than traffic has grown, so that the numbers of persons killed or seriously injured annually have fallen.

Within those transportation totals, it appears that risks have continued to decrease in passenger aviation and in trucking since deregulation. To the extent that deregulation has caused an increase in the use of smaller aircraft, some elevation of risks might be expected, but the reduction in risks from diverting traffic from road to air is likely to be much larger. In trucking, both the increase in truck traffic stimulated by deregulation and traffic diversion from rail are likely to increase truck accidents and the risks to other road users from trucks. There has been a strong downward trend in road accident risks, however, and improvements in vehicle and road technology, and in driver behaviour suggest that this will continue.

## 1.1 RELATIVE RISKS IN THE PASSENGER MODES

Table 8(2)-1 (which repeats Table 8-9 from Volume 1 of this report), provides two main safety indicators for comparisons among the passenger transportation modes. The first is the total numbers of persons killed in passenger operations — whether passengers, crew or bystanders — per billion pass-km. This indicator is referred to in Volume 1 as the "fatality rate in passenger operations." The importance of this indicator emerges when considering major changes in the extent of those operations, or major shifts among the modes, as it indicates how the total number of transportation-related deaths might change. The second indicator is the number of passengers killed per billion pass-km, referred to in Volume 1 as the "passenger fatality rate." This is the main indicator of the relative safety of passengers using the different modes, and is therefore of most interest to the travelling public.

Table 8(2)-1 illustrates these two fatality rates for the ground transportation modes and for three groups of air carriers. The following discussion describes those rates and considers possible trends for each mode.

*Table 8(2)-1*

*FATALITY RATES[a] PER BILLION INTERCITY PASSENGER-KILOMETRE BY MODE*

| Mode | Passenger fatality rate[b] | Fatality rate in passenger operations[c] |
|---|---|---|
| Air — Level 1 carriers[d] | 0.05 | 0.05 |
| Air — Level 2 carriers[d] | 0.7 | 1.0 |
| Air — Level 3 to 6 carriers[d] | 14.0 | 28.0 |
| Train | 0.8 | 13.8 |
| Bus | 0.0–1.0 | 2.0 |
| Ferry | 0.2 | 0.5 |
| Car | 10.0 | 13.0 |

a. Based on the 1980s as a whole, or recent years in 1980s.

b. Includes only passengers killed.

c. Includes passengers, crew and bystanders killed during passenger operations.

d. Includes all Canadian-registed carrier opeartions, domestic and international.

The many qualifications to these estimates follow. Important among them are that the traffic estimates are very rough for road transport, and that while all estimates are recent, they are not necessarily current. (The aviation and rail estimates are averaged over the last decade, for example, while the bus estimates are derived from accidents over a more limited period.) More importantly, the estimates are system-wide averages, and the trips — particularly their lengths — differ substantially by mode.

Within each mode, it is probable that risks are lower for longer trips. This is certainly the case for air travel, in which the risk falls with increasing stage length because of the dominance of the risks of landing and take-off, and because longer trips tend to be made in more reliable aircraft. It is probably also the case with rail travel, because longer trips are usually made over better-quality track (fewer grade crossings, in particular), and with bus travel, because the roads used are likely to be of better quality (divided highways, for example). For private motor-vehicle travel, better-quality roads will also be used on longer trips and, perhaps more importantly, the trips are more likely to be made in daylight, by experienced and unimpaired drivers using larger vehicles.

The qualifications on these estimates are particularly important in considering the effects of traffic shifting from one mode to another. For example, Table 8(2)-1 shows that shifting traffic from private motor vehicles to aircraft could save nearly one fatality for each 75 million pass-km, or that shifting 1% of highway car traffic to airplanes could prevent 27 deaths.[3] The true effects would probably be much less spectacular because the length of the trips that shifted would probably have a lower fatality rate than the road average, but would probably sustain a higher fatality rate than the air average.[4]

# 2. SUMMARIES OF SAFETY BY MODE

Each of the modes is summarized here, focussing on passenger safety. Then, some aspects of heavy truck safety are considered, and finally a brief summary of developments in road safety is provided.

## 2.1 AVIATION SAFETY

Statistics on aviation accidents are available from the Transportation Safety Board, together with estimates of hours flown by type of operation. Statistics Canada provides estimates of pass-km for air carriers. The relevant figures and derived estimates of aviation risks for the years 1981 to 1990 are shown in Tables 8(2)-2 to 8(2)-8. Table 8(2)-3 shows that 1,176 people died in aviation accidents during the decade; approximately half in private-flying and half in commercial operations. Of 607 killed in commercial aviation, only 68 flew with Level 1 or 2 carriers; the remainder flew with smaller carriers.

Aviation accidents and fatalities are so rare that they vary substantially year to year, making estimation of accident rates per unit of traffic uncertain. Those rates may be calculated for each year per 100,000 flying hours, which is the industry measure common to all types of traffic. As shown in Tables 8(2)-4 and 8(2)-6, even the annual rate for total aviation fatalities fluctuates substantially, and annual rates for the separate types of traffic fluctuate more than this. For Level 1 and 2 carriers, the single accidents in 1983 and 1989 (Cincinnati and Dryden) changed the annual fatality rates dramatically. To compare these services with the other types of traffic, it is necessary to average the rates over the entire decade (or another long period). Table 8(2)-6 shows that between 1981 and 1990 the rate of fatalities per 100,000 hours for private aviation was more than double the rate for all commercial aviation. For Level 1 and 2 carriers combined, the fatality rate was only one fifth of that for other levels of carriers, and Level 1 carriers had about one twentieth of the fatality rate of Level 2 carriers.

Given that smaller aircraft have slower operating speeds, the disparity in the rates of fatalities per kilometre flown would appear even greater between private and commercial services, and within the commercial services, between levels of carrier. Unfortunately, kilometres flown are not available for private aviation.

The comparisons rates of fatalities per pass-km among the various types of carrier, and how these rates change over time are of particular interest to the Royal Commission. Published data do not distinguish passengers from other fatalities (such as crew and others), so the major indicator that can be calculated is the "fatality rate in passenger operations." Tables 8(2)-7 and 8(2)-8 offer the relevant data. Again, to smooth the annual fluctuations, comparison is best made over the entire decade. Over the decade, Level 1 carriers provided about 95% of all pass-km by commercial carriers, with a fatality rate of 0.048 per billion pass-km, in other words, only one death every 20 billion pass-km. For Level 2 carriers, the rate was 1.0 fatality per billion pass-km (heavily influenced by the single Dryden crash), while for other levels of carriers the rate was as high as 28 deaths per billion pass-km, but their share was only 3.5% of all commercial pass-km.[5] For Levels 1 and 2 combined (the two national carriers, main feeders and charter operators), the fatality rate was 0.13 deaths per billion pass-km, one death every 7.7 billion pass-km.

Within those broader rates of fatalities in passenger operations, the passenger fatality rate can be distinguished using unpublished information provided by the Transportation Safety Board, which separates deaths of passengers from those of crew and others.[6] Figures obtained are aggregated over the decade 1981 to 1990, and show the following:

| **Class of carrier** | **Deaths of passengers** | **Deaths of others** |
|---|---|---|
| Level 1 | 23 | 0 |
| Level 2 | 34 | 11 |
| Levels 3 to 6 | 270 | 269 |
| All | 327 | 280 |

## AVIATION SAFETY INDICATORS, 1981 TO 1990

### Table 8(2)-2
### AVIATION OPERATING HOURS

| Year | Hours of operation in year (thousands) | | | | | | |
|---|---|---|---|---|---|---|---|
| | Level 1 carriers | Level 2 carriers | Other carriers | All commercial | Private | Govt. | Total |
| 1981 | 661 | 147 | 1,853 | 2,662 | 1,332 | 126 | 4,119 |
| 1982 | 621 | 110 | 1,612 | 2,343 | 1,212 | 133 | 3,689 |
| 1983 | 588 | 111 | 1,474 | 2,173 | 1,150 | 124 | 3,447 |
| 1984 | 611 | 114 | 1,452 | 2,176 | 1,027 | 119 | 3,322 |
| 1985 | 660 | 154 | 1,390 | 2,204 | 934 | 118 | 3,256 |
| 1986 | 690 | 172 | 1,441 | 2,303 | 764 | 105 | 3,173 |
| 1987 | 705 | 182 | 1,533 | 2,421 | 800 | 100 | 3,321 |
| 1988 | 759 | 384 | 1,456 | 2,600 | 800 | 100 | 3,500 |
| 1989 | 677 | 405 | 1,618 | 2,700 | 800 | 100 | 3,600 |
| 1990 | 690 | 641 | 1,369 | 2,700 | 800 | 100 | 3,600 |
| All | 6,662 | 2,421 | 15,199 | 24,282 | 9,619 | 1,126 | 35,027 |

| 1990 | 0.000 | 0.000 | 13.852 | 0.677 | | | |
| All | 0.048 | 0.981 | 28.048 | 1.123 | | | |

**Source: Calculated from data in Tables 8(2)-3 and 8(2)-7.**

Dividing these figures by the pass-km travelled by carriers of each level (given in Table 8(2)-7) results in passanger fatality rates per billion pass-km as follows:

| **Class of carrier** | **Fatalities per billion pass-km** |
|---|---|
| Level 1 | 0.048 |
| Level 2 | 0.741 |
| Levels 3 to 6 | 14.050 |
| All levels | 0.605 |

While these rates represent the decade's experience, it must be emphasized that the rates for Level 1 and 2 carriers are the result of an extremely small number of crashes, and may change radically in a short period due to the large numbers of passengers potentially involved in single events. At the time of writing, it is known that a single crash of a Level 2 carrier's aircraft in 1991 has changed the 10-year average radically.[7] This event has not been included in the intermodal comparisons in the Royal Commission's report, in consequence of a decision to standardize information by using the most recent decade (1981 to 1990) for which data are currently available in most of the modes.

### 2.1.1 How is Passenger Aviation Safety Changing over Time?

From the information in Tables 8(2)-2 to 8(2)-8, it appears that the fatal accident rates and fatality rates per pass-km for all commercial operations have improved over the decade. Examining the rates by level of carrier, however, shows that the trend was determined essentially by the experience of the smaller carriers. The infrequency of crashes among Level 1 and 2 carriers makes it impossible to determine whether their safety has improved over the period, or to make a confident estimate of the expected fatality rates for those carriers in the immediate future.

For greater confidence, we can look to safety experience in the United States, which has similar aircraft and operating conditions, but much larger numbers of operations and pass-km. We have no reason to believe Canadian carriers have worse safety records than their U.S. counterparts (and some evidence that Canadian safety records are better). In the United States, we can see a 30-year trend of reductions in accidents and fatalities per billion pass-km.[8]

### 2.1.2 What Has Been the Effect of Airline Deregulation on Safety?

The effect of Canadian deregulation in stimulating Level 1 and 2 carriers' traffic can be seen in Tables 8(2)-2 and 8(2)-7. No effect on aviation fatalities can be discerned, because of the uncertainty in estimating fatality rates in the short term. The hypothesis that deregulation would reduce profitability and lead to cuts in safety was tested to some extent in a recent Canadian study.[9] While the study found some intriguing evidence that spending by carriers on maintenance is associated with lower rates of accidents (broadly defined), it found no relationship between the profitability of carriers and their overall accident experience.

We can turn again to the United States, which has much larger numbers of flights and pass-km, for evidence of the safety effect of deregulation. Several experts have concluded that U.S. deregulation has not led to a degradation of safety.[10] Since deregulation in 1978, accident rates have followed the downward trend established in the regulated period. Moore shows that, during the period 1979 to 1986, total air carrier accidents, fatal accidents and fatalities all declined by over 40% compared with the period 1971 to 1978, and the rates per flight hour declined even more.[11] Oster and Zorn compare the period 1979 to 1985 with 1970 to 1978, and conclude that for all U.S. domestic scheduled services, fatal accidents per million aircraft departures more than halved from 0.46 to 0.22, while passenger fatalities per million passenger enplanements fell from 0.42 to 0.30.[12]

There had been concern that deregulation would switch traffic from major carriers to commuter carriers, and that the latter had worse safety records. Comparing the same periods, however, showed only slightly greater growth in flight hours for air taxis and commuter airlines than for scheduled large jet air carriers (29.8% versus 26.1%).[13] More importantly, passenger safety was shown to improve more for smaller carriers than for larger carriers. Oster and Zorn show that on domestic scheduled services, fatalities per million passengers remained essentially unchanged among trunk carriers, and also among the 20 largest commuter carriers, but fell by over 60% among the smaller commuter carriers.[14] They explain that much of the reduction resulted from a change in average stage length among the commuter carriers. The records of commuter carriers per pass-km reflect their shorter average stage lengths, and the fact that rates of accidents and deaths fall with increased stage length because the risks are much lower when cruising compared with landing or taking off. (This also partially explains the apparently higher fatality rates of Canadian Level 2 carriers compared with Level 1, and of Levels 3–6 carriers compared with Level 2.) The switch to commuter lines following deregulation was part of the hub-and-spoke development, which actually reduced the number of stops on a typical passenger's flight, thereby substantially improving the commuter carriers' safety.[15]

Overall, researchers reach the cautious conclusion that, although the increase in commuter traffic possibly raised average risks per pass-km compared with what might have occurred without deregulation, air safety continued to improve.

Furthermore, commentators note that, to the extent that aviation deregulation diverted traffic from road to air travel, the safety of that traffic improved substantially (see notes on road passenger risks). A study by Bylow and Savage uses a model of highway travel demand to estimate the reduction in road travel as a result of airline deregulation, and then uses U.S. rural highway fatality rates per vehicle-kilometre to estimate the reduction in highway deaths. The authors suggest that highway deaths were reduced by 3,000 over the period 1978 to 1988, dwarfing estimates of the effects of deregulation in raising the risk of air fatalities.[16]

## 2.2 RAIL SAFETY

Major indicators of rail safety are provided in Tables 8(2)-9 to 8(2)-12. Table 8(2)-9 first shows deaths arising from all rail operations, most of which transport freight, of course. Over the decade to 1990, there was a total of 1,255 deaths. Half occurred in grade crossing accidents, and nearly all were occupants of the motor vehicles struck. Another 40% were persons struck by trains, either employees, or persons walking on tracks, including suicides. Only 54 deaths (less than 5% of the total) came from collisions or derailments, and 24 of these occurred in a single crash in 1986 at Hinton, Alberta.

The annual total of fatalities declined fairly steadily through the decade. Table 8(2)-10 shows that train-kilometres also declined, but less than fatalities, so the overall fatality rate per train-kilometre declined slightly over the period. Among the accident types, deaths in collisions and derailments are so rare that annual rates per train-kilometre are too unstable to show trends. Little change over time can be discerned in the death rate of persons struck by trains, but some improvement does seem to have occurred in the rate of deaths from grade crossing accidents.

| All | 24,108 | 0.830 | 0.332 | 7.217 | 5.517 | 13.896 |

**Sources: Intercity pass-km from Statistics Canada, *Railway Transport: Part IV, Operating and Traffic Statistics*, Catalogue No. 52-210, to 1981, and unpublished data thereafter, with interpolation for 1990 from VIA Rail annual report; fatality rates calculated by Royal Commission staff from pass-km plus data from Table 8(2)-11.**

The safety of passenger rail operations is portrayed in Tables 8(2)-11 and 8(2)-12 (provided by the Transportation Safety Board from unpublished tabulations). Passenger fatalities averaged about two per year, but there were no deaths in eight of the years, and 16 deaths in 1986 in the single crash at Hinton. Over the decade, passenger operations also resulted in eight crew deaths, 174 deaths at grade crossings, and the deaths of 133 trespassers.

Table 8(2)-12 shows that pass-km on intercity rail services fluctuated somewhat during much of the decade, but then dropped by nearly half in 1990, following the major cuts in VIA Rail services. The same Statistics Canada source shows that commuter pass-km rose over the period, comprising 13% of total pass-km in 1981, and 19% in 1988. The fatality rates in Table 8(2)-12 (and in Chapter 8 of Volume 1 of this report) are expressed relative to pass-km for intercity services, while the fatality estimates in Table 8(2)-11 include deaths occurring in commuter services. The fatality rates are therefore somewhat overstated. Table 8(2)-12 first shows the passenger fatality rate for the decade, averaging 0.83 deaths per billion intercity pass-km. It then shows fatality rates for each of the types of non-passenger, and finally totals the overall fatality rate in passenger operations, which averaged 13.9 over the period. It can be seen that the annual passenger fatality rate per pass-km is subject to major, erratic variation because of variability in the frequency of deaths, and therefore no trend can be recognized. The annual total fatality rate in passenger operations is less variable, but shows no trend over this relatively short period.

## 2.3 INTERCITY BUS SAFETY

Statistics describing the safety of intercity bus operations are very sparse. Provinces and territories are responsible for their own road accident reporting systems, and none routinely reports the total numbers of casualties cross-referenced to the types of vehicles involved in the accidents. Only five jurisdictions (Saskatchewan, Manitoba, Ontario, Nova Scotia and Newfoundland) have distinguished intercity buses from transit buses in their police report forms and computer systems. All jurisdictions recently agreed to report annually to the Canadian Council of Motor Transport Administrators the number of victims killed and injured in intercity buses as part of the effort to monitor the impact of deregulation and the National Safety Code. Their agreement, however, has not been implemented.

Table 8(2)-13 presents a special tabulation from Transport Canada's provincial and territorial computer files showing victims killed and injured in accidents involving intercity buses in the five provinces listed.[17] The table combines the numbers for the three years from 1985 to 1987, showing a total of seven deaths and 265 injuries in these accidents. Of these, no bus occupants were killed, and 27 bus drivers and 73 bus passengers were injured. All seven deaths, and 135 of the other 165 injured, were occupants of other vehicles, which were nearly all cars or light trucks. Only four of the bus occupants and 17 of the other victims were injured severely enough to require hospitalization.

*Table 8(2)-13*

*INTERCITY BUS ACCIDENT VICTIMS, FIVE PROVINCES,[a] 1985 TO 1987*

| Victim type | Severity of Injury[b] | | | |
|---|---|---|---|---|
| | Minimal | Minor | Major | Fatal |
| Bus driver | 16 | 10 | 1 | 0 |
| Bus passenger | 51 | 19 | 3 | 0 |
| Occupant of other vehicle | 74 | 47 | 14 | 7 |
| Motorcyclist | 2 | 3 | 0 | 0 |
| Bicyclist | 2 | 5 | 0 | 0 |
| Pedestrian | 5 | 10 | 3 | 0 |
| All | 150 | 94 | 21 | 7 |

**Source: Personal communication between staff of Transport Canada and Royal Commission staff.**

**a. Saskatchewan, Manitoba, Ontario, Nova Scotia and Newfoundland.**

**b. Minimal — no treatment required;**
**Minor — treated but not admitted to hospital;**
**Major — admitted to hospital.**

This tabulation can offer no indication of trends over time, and suggests that the annual numbers would be too small to allow trends to be recognized easily even if a long series were available. It is possible only to speculate about trends, but it is relevant that the majority of victims in these accidents were in cars and light trucks, and it is known that the accident rates and "crashworthiness" of those vehicles (the ability of occupants to survive crashes) have improved over time. Improvement will likely continue as accident avoidance capabilities are developed (for example, through anti-lock braking systems, hazard detection systems, and the vehicle guidance aspects of "intelligent vehicle-highway systems"), crashworthiness is improved (through air bags and enhanced side-impact protection) and seat belts are used more consistently.

No estimates of the death and injury rates per intercity bus vehicle-kilometre and pass-km can be made confidently from the information available, particularly as we have no estimates of pass-km travelled in the five provinces concerned. Making the very heroic assumption that the ratio of intercity bus casualties to total road casualties in these five provinces is the same in other jurisdictions, it is possible to estimate total casualties in intercity bus accidents for the three years from 1985 to 1987 as approximately 17 fatalities and 500 injured. Total national traffic in intercity bus services in 1991 is estimated by Royal Commission staff as 3.3 billion pass-km. If traffic was at that same level during 1985 to 1987, the total for the three years would have been 9.9 billion pass-km, and the average risk of fatalities in passenger operations for the period would therefore have been 1.7 deaths per billion pass-km. Due to the uncertainty in both the number of deaths and the traffic estimates, this fatality rate is rounded in Chapter 8 of Volume 1 of this report as 2.0 deaths per billion pass-km.

From the information available, none of the victims during these three years was a bus occupant, so the estimated bus passenger fatality risk would be zero — clearly incorrect as a representation of the long-term risk. To provide some indication of the likely risk, in order to make intermodal comparisons in Volume 1 of this report, it is guessed that passenger fatalities constitute less than half the total fatalities in bus operations. Noting that passengers constituted 73 of the total of 265 injured victims, the true bus passenger risk would lie somewhere between 0 and 1.0 deaths per billion pass-km.

## 2.4 FERRY SAFETY

Statistics from the Transportation Safety Board (unpublished tabulation) on passenger deaths on ferries are summarized in Table 8(2)-14. These relate to all ferries in Canada, not just the longer services on which the Royal Commission has focussed in Volume 1.[18] The table distinguishes the latter "intercity" ferries from those relating to "river or harbour crossings," showing that six passengers died on intercity ferries during the decade to 1990, of a total of 20 passenger deaths on all ferries.

*Table 8(2)-14*
*PASSENGER DEATHS IN ACCIDENTS ABOARD FERRIES*

| Year | Intercity ferries | River/harbour crossings | Total |
|---|---|---|---|
| 1981 | 1 | 3 | 4 |
| 1982 | 1 | 3 | 4 |
| 1983 | 0 | 1 | 1 |
| 1984 | 0 | 3 | 3 |
| 1985 | 1 | 1 | 2 |
| 1986 | 2 | 0 | 2 |
| 1987 | 0 | 0 | 0 |
| 1988 | 1 | 0 | 1 |
| 1989 | 0 | 0 | 0 |
| 1990 | 0 | 3 | 3 |
| All | 6 | 14 | 20 |

**Source: Personal communication between Transportation Safety Board staff and Royal Commission staff.**

Fatalities in ferry passenger operations should also include deaths of crew and any other non-passengers. Other unpublished statistics from the Transportation Safety Board show that there were a total of 26 deaths aboard or involving ferries during the decade.[19] From this it can be deduced that six of those who died were not passengers. The proportion of those non-passenger deaths occurring in the intercity services is not known, but, if similar to the proportion among passenger fatalities, would mean that two of the six were in intercity services. The total number of deaths in intercity passenger ferry operations during the decade is therefore estimated at eight.

To assess risks associated with ferry transport, these rough estimates of fatalities are converted to annual averages. Passenger fatalities amounted to about 0.6 per year during the decade, and total fatalities in passenger operations to about 0.8 per year. Passenger-kilometres are not available in traffic records for the whole decade, but have been estimated, in the Notes to Chapter 3 of this report, for all the intercity ferries, at about 830 million pass-km in 1990. Assuming that the average annual fatalities for the decade were constant,[20] estimated risks for passenger deaths are 0.7 deaths per billion pass-km, and for fatalities in passenger operations about 1.0 deaths per billion pass-km.

## 2.5 PRIVATE MOTOR-VEHICLE SAFETY IN INTERCITY TRAVEL

The aggregate risks associated with intercity passenger travel by private motor vehicles (cars, vans and light trucks) can be roughly estimated as follows. Transport Canada statistics of motor-vehicle traffic accidents provide the number of fatalities on roads with speed limits greater than 60 km/h — including highways and local rural roads. In 1989 there were 2,808 such fatalities, constituting 65% of total motor vehicle fatalities for the year.[21] The Royal Commission's estimate of total highway passenger-vehicle traffic for the year was 210 billion pass-km. Comparing the two gives a fatality rate of 13 per billion pass-km, or one fatality for every 80 million pass-km. In addition, we can estimate the rate of persons injured (of all severities) as 440 per billion pass-km.

The passenger fatality rate in road use is interpreted differently than in the public transport modes because there is no important distinction between private vehicle passengers and "crew." Private vehicle operators are nearly always travellers themselves (professional drivers being rare exceptions), and so should be included in the calculation of a passenger fatality rate. This rate differs considerably from the fatality rate in passenger operations, because private-vehicle occupants (drivers and other occupants) constitute about 80% of the total fatalities. The remainder are pedestrians, motorcyclists, bicyclists or occupants of vehicles of other types (heavy trucks, mobile equipment, and so on). In 1989 the passenger fatality rate was about 10 per billion pass-km.

## 2.6 HEAVY TRUCK SAFETY

As in the intercity bus case, information on truck safety has not been routinely available due to the failure of the provinces and territories to tabulate their records of accident victims by vehicle type. Limited information has become available recently as a result of the agreement through the Canadian Council of Motor Transport Administrators to monitor the effects of the National Safety Code. (This information provides the input to Transport Canada's annual report to Parliament on "Commercial Vehicle Safety in Canada," required under the *National Transportation Act, 1987*.) The information is limited particularly because it provides no details on the number of accident victims. Instead, it merely indicates the number of accidents of each severity in which heavy trucks were involved. These numbers are provided for the years 1986 to 1988 in Table 8(2)-15.

Traffic data comparable with the accident information in Table 8(2)-15 are not available. National compilations of the numbers of vehicles registered do not even distinguish heavy trucks from light trucks (that is, pickups and small vans, which probably outnumber heavy trucks by 10 times). No vehicle-kilometre information exists beyond that obtained for part of the heavy truck fleet from Statistics Canada's surveys of major carriers and partial surveys of private trucking. For some provinces, it is possible to estimate that heavy trucks account for about 3% of vehicles registered. By extrapolation, one can roughly estimate that they account for 9% of total vehicle-kilometres by road.[22] In contrast, the table shows that trucks were involved in slightly less than 3% of non-fatal injury accidents in each of the three years, but in about 9% of all fatal accidents. It seems likely that trucks are substantially under-involved in accidents relative to their vehicle-kilometres travelled — that is, they are less likely to crash per vehicle-kilometre than cars — but when accidents occur the greater weight of the trucks makes the consequences more severe.[23]

*Table 8(2)-15*
*HEAVY TRUCK INVOLVEMENTS IN ACCIDENTS, 1986 TO 1988*

| Fatal accidents | | | | | | |

Just how severe is shown in Table 8(2)-16, which compares injuries sustained by the truck occupants with those of the other victims in these accidents. From a large sample of heavy truck accidents analyzed by Transport Canada staff,[24] the table shows that a total of 90 truck occupants were killed and 4,078 injured. About half of these were single-vehicle accidents. Non-truck victims accounted for 392 deaths and 6,806 injuries. Sixty-seven of those killed were pedestrians, bicyclists or motorcyclists — the most vulnerable road users — and the other 324 were occupants of cars or light trucks. Accidents involving cars or light trucks illustrate the disproportion in risks faced by the light and heavy vehicle occupants: the accidents produced 27 times as many deaths in light vehicles as in heavy trucks (324:12), and 4.6 times as many injuries.

*Table 8(2)-16*

*HEAVY TRUCK OCCUPANT CASUALTIES (SAMPLE 1984 TO 1986)*

### 2.6.1 Effects of Increasing Truck Sizes

Canada allows substantially larger and heavier trucks to use its highways routinely than does the United States, particularly since the signing of a Memorandum of Understanding among provinces and territories in September 1989.[25] This agreement followed extensive review of the issue of the safety of various trucks, and original work (by the National Research Council, through TAC) on the stability of heavy truck configurations. Evidence on the safety of different classes of truck from over-the-road experience is confounded by differences in operating conditions. Studies find lower accident involvement rates for combination trucks (various tractor and trailer configurations) than for the lighter and shorter straight trucks, and lower rates for double-trailer combinations than for single trailers.[26] It is clear that the larger, heavier trucks operate in more favourable conditions, in particular on major rural highways that have lower accident rates for all traffic, and probably operate with more experienced and capable drivers. Comparing trucks under similar conditions, the U.S. Transportation Research Board finds that the accident and fatality rates of trucks increase with gross weight and dimensions, but by much less than the carrying capacity.[27] This suggests that transferring loads to larger trucks, and therefore using fewer trucks for a given tonnage of freight, improves safety per tonne-kilometre.

### 2.6.2 Effects on Safety of Trucking Deregulation

Table 8(2)-15 can also be examined for evidence of trends in the three years, the latter two of which followed deregulation of trucking. The numbers concerned are small, but do seem to indicate that the accident involvement of heavy trucks increased after 1986, relative to all other vehicles. This is more pronounced for fatal accidents than non-fatal, and appears confined to "straight trucks" rather than tractor-trailer combinations. No traffic information is available, however, to explain whether this represents an increase in the fatal accident rate per vehicle-kilometre, an increase in vehicle-kilometres, or any change in operating conditions.

Evidence from the United States, which has many more trucks and accidents, allows more precise assessments. The conclusions of a seminar held in 1987 were that truck safety has continued to improve during the period since deregulation (a reduction from 64 fatal accidents per billion vehicle-kilometres in 1978, to an average of 54 between 1983 and 1985).[28] The U.S. Department of Transportation concluded more recently that, from 1977 to 1988, the rate of fatal crash involvements for single-unit trucks fell by one third, and the rate for combination trucks by 40%, while the rate for passenger vehicles declined by 25%.[29]

## 2.7 OVERALL TRENDS IN ROAD SAFETY[30]

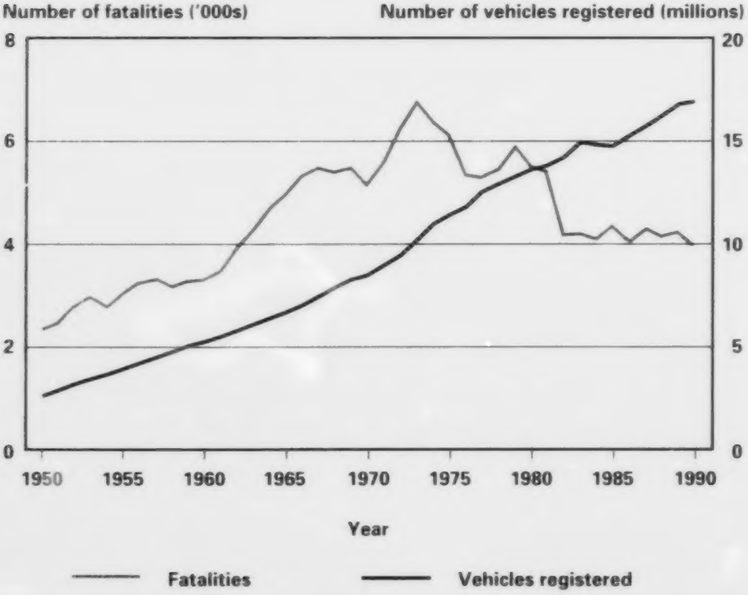
---

The trends in road traffic and safety from 1950 to 1990 are illustrated in Chart 8(2)-1 by two main indicators: the size of the motor vehicle fleet and the number of road accident fatalities. (Consistent estimates of vehicle-kilometres are not available.) Road traffic has grown almost without interruption since the invention of the motor vehicle. Since 1950, the vehicle fleet has become six times as large. The chart shows that deaths have increased with traffic, but not consistently. The number of deaths grew until 1973, and fell since then, but with substantial perturbations in the trend. Fatalities approximately trebled between 1950 and 1973, from 2,272 to 6,706. During this 24-year period, a total of 98,196 people died in road accidents.

Extrapolation of the simple trend observed prior to the year 1973 suggested that a further 230,000 would die in road accidents between then and the end of the century; and that over 130,000 would die between 1973 and 1990. In fact, the trend in fatalities changed quite abruptly after 1973. Since then, the annual toll has fallen almost every year. In 1990, it was 3,957, which was 40% lower than in 1973,

*Chart 8(2)-1*

*TRENDS IN ROAD TRAFFIC AND SAFETY, 1950 TO 1990*



and lower than in any year since 1962. For the period 1974 to 1990, the total deaths were 82,619, but this was one third lower than was predicted from the trend prior to 1973.

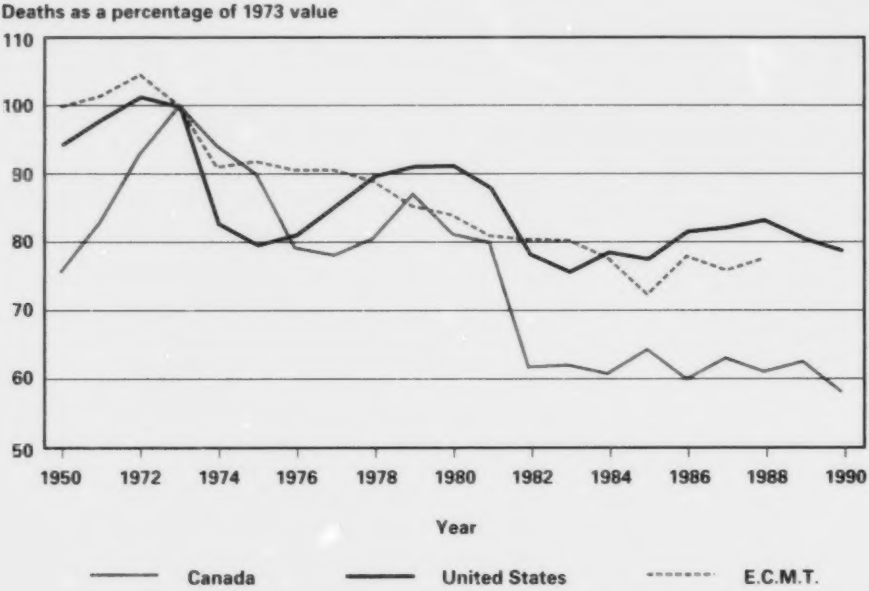
The trend to 1973 was of a long-term decline in the average rate of fatalities per vehicle as the vehicle fleet grew. There were, however, substantial fluctuations in that trend, including some sustained periods, such as 1961 to 1966 and 1970 to 1973, when fatalities grew faster than the vehicle fleet and faster than total traffic. Such periods can be shown (in other developed countries as well as Canada) to coincide with spurts in economic growth.[31]

Since 1973, the decline in the average fatality rate has been much sharper, and rose only in 1979 and 1985. While the rate of deaths per 10,000 vehicles fell from 8.7 to 6.6 in the 23 years between 1950 and 1973, it then fell by more than two thirds to 2.3 in the next 17 years to 1990. The sharpest reductions in the fatality rate occurred in 1974 and 1982, which were years of depressed economic activity. But strong economic growth between those years brought no more than a slight increase in deaths in 1979, and sustained growth from 1982 to 1989 produced no increase. It seems safe to conclude that a fundamental improvement in safety — a change in the underlying relationship of fatalities to traffic — has occurred since 1973.

Chart 8(2)-2 supports this conclusion with simple comparisons of trends in Canada with those in other developed countries. The chart shows fatalities represented by indices, with 1973 levels set to 100, for Canada, the United States, and a combined group of 19 countries of the European Conference of Ministers of Transport (ECMT). It is clear that there has been a much greater proportional reduction in fatalities in Canada than in these other countries since 1973, particularly since 1981.

*Chart 8(2)-2*

*INDEX OF FATALITIES, 1973=100*



Some major aspects of these improvements are summarized below.

*(i) Deaths by type of road user:* Driver fatalities have remained almost constant over the past couple of decades, and now amount to about 1,900 annually; while those of passengers have fallen to about 1,100 per year reflecting reductions in vehicle occupancies with increased motorization. Pedestrian deaths have shown the largest reduction, and there are less than half as many deaths (600) as 20 years ago. Motorcyclist deaths increased until about 1983, but have since declined by 40% to about 250 per year; and bicyclist deaths have remained relatively constant, at about 100 deaths a year.

*(ii) Deaths by age-group:* Assessing the period from 1957 to 1987 shows:

- Age-group 0 to 4 contributes only about 2% of deaths; the fatality rate per capita is less than one third of the average for all groups and has fallen faster than the average; the population of the group fell by 9%.

- Age-group 5 to 14 contributes about 6% of all deaths; the fatality rate per capita is less [illegible] half the average; population of the group declined 21% in the period.
- Age-group 15 to 24 contributes nearly 30% of all deaths — a remarkable over-representation; the fatality risk per capita is two and a half times that of the average of the other age-groups, but has recently fallen faster than the average; the population is larger than in 1970, but has contracted since 1980.
- Age-group 25 to 64 contributes 50% of all deaths; the fatality rate per capita fell overall by 40% over 20 years; the population grew by about 50%.
- Age-group 65 and over contributes nearly 15% of total deaths; the rate of fatalities per capita is slightly higher than the average for all age-groups and is falling faster than the average over the period; but growth in the population of the age-group is stronger than the reduction in its fatality rate per capita, so the absolute number of deaths in the group is rising.

### 2.7.1 Effects of Safety Measures

These trends show that the decline of fatalities in Canada can be explained partially through demographic changes, but mostly remains unexplained. The information available on the effectiveness of programs in road improvement, vehicle performance regulation, or road user education and control, however, is surprisingly poor. The complex relationships among contributing factors, and the poverty of data describing them, have meant that efforts at modelling and explaining the processes have not been very successful. Gaudry's modelling of relationships between social factors and accidents in Quebec is unusual in allowing recognition of the influences of a number of the factors with some statistical confidence.[32] But the introduction of safety measures is rarely immediate enough or sufficiently widespread so that the effects could be assessed accurately even with such a model.

Furthermore, an intriguing aspect of the overall trends is that, in one way, they appear simple to describe: that is, in the long-term decline in the fatality rate per vehicle (or vehicle-kilometre). Researchers have shown in a number of countries that a simple curve describes how the fatality rate declines as the level of motorization (vehicles per capita) grows.[33] They further suggest that the relationships are very similar in many countries — in other words, that different countries have very similar fatalities per vehicle at the same level of motorization. Although this generalization is attractive, it would worry safety programmers because it suggests that safety programs are a waste of time and that improvement over time is inexorable with increasing motorization.

The notion of such a simple determination of the fatality rate is countered by evidence that there are important changes in the relationship over time in any country, and among countries.[34] A substantially different interpretation of the change in the fatality rate over time has recently emerged, particularly from researchers at the Institute for Road Safety Research in The Netherlands.[35] They suggest that the trend in the fatality rate can best be described by a very simple relationship derived from mathematical "learning theory." This they interpret to mean that the phenomenon of a declining fatality rate results from "social learning" about safety — a growing understanding by all involved of the means of controlling motorization. The part played by all the various safety programs still remains conjectural — these researchers suggest that the progressive implementation of safety measures has been part of social learning, but have no specific evidence for their effects.

Such evidence should have accumulated from evaluations of specific safety measures using laboratory experiments, or careful observations of the effects of measures that have been implemented. Unfortunately, it has proven difficult to predict from laboratory experiments how safety measures will be received when implemented (for example, how drivers will react to changes in road markings, or to improvements in vehicle performance). In particular, it has been found that road users adapt their behaviour to changes in equipment or controls, and often in a way that reduces the intended safety gain.[36] One hypothesis has held that adaptation is intended to keep risks constant,[37] while other empirical evidence shows that the extent of adaptation is unpredictable.[38]

To identify the effects specific to a safety measure, evaluations of its implementation attempt to control for changes in traffic and other extraneous factors. Unfortunately, most evaluations are controlled poorly, and many evaluations are subject to upward biases in their estimates of safety improvements,[39] so all claims for the effects of preventative measures should be viewed with great suspicion.

In sum, there are not many measures that safety researchers would agree have been demonstrated to be effective. The list would probably include:

- a number of major highway improvements (generally for capacity expansion purposes), including grade separation, straight and flat alignments, and paved shoulders;
- guardrails, crash barriers and edge-linings;
- minor improvements on roads at "black spots," for example, to sight-lines, surface conditions, traffic signs and controls;[40]
- a number of U.S. and Canadian motor vehicle performance standards, particularly those for crashworthiness, including standards for deflecting steering columns, side door beams, windshields, door locks, seat belts and air bags;[41]
- seat-belt use laws and their enforcement;[42] and
- random breath testing to enforce laws against drunk-driving.[43]

The list would probably not include some very popular remedies, such as motor vehicle inspection,[44] high-school driver education,[45] and most public information campaigns.[46]

### 2.7.2 Possible Future Trends

Some of the trends noted earlier can be expected to continue. One of the major changes noted was the disproportionate reduction in pedestrian and passenger fatalities. The reduction in pedestrian fatalities should slow because the changes were proportionately so large, and because underlying contributors, such as the decline in the child population and school consolidation, have slowed. Passenger fatalities could continue to drop relative to driver fatalities if the vehicle fleet continues to grow faster than the population, because vehicle occupancies could be expected to continue to fall.

The effects of future demographic trends must also be factored into the predictions. The contraction of the youngest age-group appears to have ceased, and the child population can be expected to be more stable in the immediate future. The group 25 to 64, with an aggregate fatality rate that is close to the average, will continue to provide the bulk of total population growth. The oldest age-group, over 64, will also continue to grow fastest, exerting an upward pressure on average fatality rates. For the next decade or so, this will be more than offset by the continuing contraction in the young adult group aged 15 to 24, with its very disproportionate risks.

Overall, none of these effects seems likely to be very dominant in changing the fatality rate from its current level. The main determinant of the change in fatalities will continue to be the change in the traffic. As represented by the size of the vehicle fleet, total traffic seems likely to follow its historical growth at a faster rate than the population.

Fatality rates, however, can probably be expected to continue to fall over time. It seems likely that driving activity will increase more in conditions with lower risks (more urban than rural driving, for example, and at slower speeds because of congestion), and among drivers with lower than average risk, as driving activity continues to broaden demographically (involving more women and older people). Reductions should be reinforced by the lagged effects of recent safety measures, and by the impacts of anticipated new measures. It can be expected that air bags will be introduced in all cars and light trucks, and that further vehicle standards will be introduced to improve crashworthiness (especially in side impacts) and crash avoidance (for example, through anti-lock brakes and hazards warning, or even automatic hazards avoidance). It can also be expected that highway safety will be improved by paving shoulders, removing roadside obstacles, and constructing further grade-separated highways.

In the longer term, the introduction of Intelligent Vehicle-Highway Systems holds the prospect of extraordinary improvements in safety (as well as traffic capacity). Once two-way vehicle communication systems are established for navigation (which will likely be broadly available in congested cities within 20 years), the development of vehicle control systems is likely to proceed swiftly, offering the possibility of vehicle queue control. Combined with the development of enhanced on-board vehicle control systems, and, ultimately, autonomous systems, these seem capable of greatly reducing crashes.

## 3. VALUES OF ACCIDENT LOSSES

### 3.1 ESTIMATES OF LOSS COSTS IN ACCIDENTS IN CANADA

Most of the work to estimate accident losses has been done in relation to road safety.[47] A number of different cost items might be distinguished:

- damage to vehicles and other property;
- health care for victims;
- lost employment and other "work efforts" of victims;
- time and efforts of police and other emergency services;
- pain, suffering or mental anguish suffered by victims and others;
- lost home, family or community services of victims;

- legal and court proceedings to establish fault, compensation, and so on;
- administration of insurance claims; and
- efforts of family or friends in attending victims.

With a little ingenuity, the list can be extended considerably to include a number of other losses and irritations that affect the victim, the family, employer and social contacts, and that require social resources to correct.

Most of the items on the list would be difficult to identify and estimate, and some might be impossible to measure. The "subjective" costs of victims' pain and suffering obviously present the most problems, but a number of other items, such as losses of services in the home or other family and community services, are normally unpaid and are difficult to assess monetarily.

Transport Canada has attempted to estimate values for all of these losses, and show that three major items dominate (in this order): property damage, lost work, and health care costs. Costs of property damage are estimated from insurance company claims records, with allowances for unclaimed damage. Costs of lost work are estimated from durations of disability and average expectations of lifetime income, with allowance for unpaid efforts at alternative market rates. Health care costs are estimated primarily from payment records from the provincially owned motor-vehicle insurance administrations in Quebec and British Columbia.

Estimates of the losses (rounded) are shown in Tables 8(2)-17 to 8(2)-21, as total amounts for the year 1990, as averages per accident by severity, and as averages per victim by severity (the average accident including more than one victim, plus property damage).

### Table 8(2)-17
### ESTIMATED VALUES OF TOTAL LOSSES IN ROAD ACCIDENTS, 1990

| Type of loss | Amount ($ billion) |
|---|---|
| Property damage | 5.0 |
| Lost work | 3.5 |
| Health care | 0.5 |
| **Total** | **9.0** |

## 3.2 HEALTH CARE LOSSES: WHO PAYS?

Surprisingly little information is available on the extent and costs of health care for victims of transportation accidents, partly because the health care system is more concerned with recording diagnoses and treatments than causes of ill-health, and partly because hospitals and provincial medical insurance schemes do not attribute treatment costs to individual victims, but average their costs per day and charge victims for the number of days treated.

The values in the tables come from Quebec and British Columbia, where the provincial motor-vehicle insurance agency reimburses the department of health for treatment of road accident victims. In both provinces, the agreed amount in each year is a lump sum estimated by the department of health as the costs it incurred.

The amounts in 1990 were about $1,250 per reported road accident victim in British Columbia, and about $2,500 per reported victim in Quebec.[48] Adjusting for a higher average severity of injury to victims in Quebec, the national average is estimated to be $1,500 to $2,000 per reported victim. In 1990, the total would be rounded up to about $500 million for the 263,000 reported victims. Note that this average per reported victim is much lower than the individual costs of treatment for those who received health care, because about 35% of all reported victims received no medical treatment, another 55% received only out-patient treatment, and only about 10% were admitted to hospital.

Of the total of about $500 million, the Quebec and British Columbia insurance corporations — through their policy-holders — paid nearly $200 million. In Ontario, since the introduction of "no-fault" motor-vehicle insurance in 1990, the entire amount has been paid from provincial medical insurance budgets — and that probably amounted to between $200 million and $220 million in 1990. (Previously, the provincial health agency was able to recuperate the costs of health care from vehicle insurance companies when their clients were found responsible, and operated a bulk payment agreement by which the companies paid a flat rate of 2.5% of liability insurance premiums to cover those health care costs.)

In Saskatchewan, the provincially owned motor-vehicle insurance corporation is held liable by the provincial health insurance systems for the health care costs of victims who are negligent in accidents, but those are a small minority of victims. (In Saskatchewan, the payment this year amounts to about $3 million.[49]) The rest of the cost is borne by provincial health insurance. In the remaining provinces, the private vehicle insurance companies can be held responsible for the health care costs of those found at fault (as used to be the case in Ontario). This must be done case by case, however, and so reimbursement is not pursued systematically — probably most often when costs are higher and negligence is more firmly established.

In summary, it seems probable that for road accident victims roughly as much as $300 million of health care costs are borne annually by health insurance plans, and about $200 million by motor vehicle owners (essentially only in Quebec and British Columbia).

For other modes, no information is available whether provincial health care authorities recover health care costs. It seems less likely that recovery would be achieved for these modes, because the assignment of responsibility is probably less formal than is the case with road accidents (where police normally determine responsibility, and fault-finding procedures are well established in insurance legislation or by customary practice). Therefore, it seems probable that health care systems and the people who pay for them meet all the costs of care for accident victims in these other modes. However, there are also many fewer casualties compared with those in road accidents. The total health care costs, in 1990, for road casualties (urban as well as interurban) related to 3,957 fatalities and 263,000 injuries. Comprehensive and comparable records of the number of injured victims in the other modes are not available, but their total annual number is likely much less than 1,000. The largest number would be in bus accidents, which subsection 2.3 suggests were about 170 annually from 1985 to 1987. The next largest group would be victims of train accidents. Transportation Safety Board records show that the ratio of injured victims to fatalities from 1981 to 1990 was fewer than five to one, in which case the annual number in accidents involving passenger trains and excluding grade crossing accident victims (counted as road accident victims) would be fewer than 80. For accidents involving aviation, in which about 60 people died annually during the decade, it seems likely that the ratio of injured to killed is very low (because aviation accidents are so severe). Finally, ferry accidents are so rare that fewer than one person was killed annually in the decade, and the number of injured was likely to be fewer than 10 per year.[50] Health care costs for all injured victims in the public modes would then have been less than $2 million in 1990, if costs per victim were the same as for road accident victims.

## 3.3 ALTERNATIVE VALUATIONS OF ACCIDENT LOSSES, FROM "WILLINGNESS TO PAY"

Academics have debated the appropriate "value of life" for a century or more. Most of the argument has centred on the value of improvements in safety brought by public investments. The predominant view among economists is currently that intangible benefits in benefit-cost analysis should be given money values based on what the beneficiaries would be willing to pay for them. The view of specialist, safety economists is also that the benefit from a safety improvement is the risk reduction gained by the population at risk, and that its value is whatever people would be willing to pay for the psychological satisfaction they gain.

From this viewpoint, the value of avoiding accidents and their consequences need bear no direct relationship to the costs of sustaining those consequences. Rather than valuing safety by adding up the costs of people dying, it proposes that we add up what the population at risk is willing to pay to reduce the specified chance of dying.

Researchers have considered the following sources:

- insurance premiums paid by individuals;
- court awards of compensation to accident victims;
- values of safety implied by previous government decisions;
- premiums received by workers in risky jobs;
- amounts paid by consumers for safety devices; and
- amounts individuals say they would pay for hypothetical risk reductions.

The first three sources are inappropriate for appraising safety improvements. Insurance premiums address only risks of personal financial losses, and cannot incorporate loss of a victim's own life or physical suffering. Court awards are circumscribed by law and precedent, and tend to be paid in unrepresentative circumstances, in which negligence can be shown, and/or losses are large. Values implied by previous government decisions reveal what hindsight shows the government to have accepted, when rarely was the trade-off explicit, and shows major inconsistencies.

The other three potential sources are cases where individuals trade money for safety, and are considered to be legitimate approaches to finding "willingness to pay" for safety. Worldwide, only about 40 of these empirical studies have been undertaken.[51] It is very difficult to find credible situations in which safety is traded for money in an identifiable way — when the change in risk that is being purchased, and the amount of money involved, are obvious to both the purchaser and the researcher.

Most of these studies compare wage premiums paid for job risks. In these studies, the researcher normally has only some broad estimates of average risks existing in various industries, and must assume that each worker recognizes and trades precisely those risks in deciding where to work. That seems implausible, as does the presumption in the studies that the risk premiums are unaffected by bargaining conditions such as trade union power.

In studies of consumer purchases of safety devices, it is even more difficult to determine what risk reduction consumers believe they are obtaining. Researchers seldom find it possible even to obtain an objective estimate of the risk reduction involved. Such studies are, consequently, extraordinarily rare. The favoured alternative approach is to consider situations in which travellers trade time for safety, and to infer a value for safety from an assumed money value for their time. These add the complications of the great uncertainties in determining values of time to those of revealing the nature of the traded risk.[52]

Finally, the survey approach, asking people the values they would pay for hypothetical risk reductions, manages to avoid the problems of recognizing the risk changes involved, as these are specified in the questions. It faces the criticism, however, that hypothetical responses might relate only poorly to behaviour, and it introduces a number of specific problems in respondents' ability to understand and manipulate small numerical risks.

The behavioural studies we reviewed provide estimates for the value of avoiding a death ranging from less than $200,000 to more than $50 million. The view of some economists[53] is that the best of these can be judged to centre on about $1 million to $3 million, and that such values should be used in benefit-cost analysis. The view of others[54] is that the results of the studies do not allow a confident finding of a central value, or schedule of values of different risks. They also believe there is currently no substitute for either using minimum values based on material losses (Tables 8(2)-17 to 8(2)-21), or obtaining a political judgement of the values of safety to use in benefit-cost analysis, based on the relative priority to be given to safety among other objectives of government action.

## 3.4 CURRENT PRACTICE AT TRANSPORT CANADA

The policy on valuing safety at Transport Canada has undergone a radical change, with adoption in 1992 of a single value for a death avoided of $1.5 million, in 1991 dollars. Recent practice differed substantially among different parts of the Department, with values in 1989 dollars varying from $310,000 in road safety evaluations to as high as $2.9 million in some aviation investment evaluations. The differences were not created by income differences in the victims (by mode), but resulted from different interpretations of the literature on willingness-to-pay valuations. The position taken for road safety evaluations was that willingness-to-pay research had not provided convincing estimates, so the value used was a minimum estimate based on material losses, while the value used in aviation evaluations reflected a judgement that some of the willingness-to-pay research provided defensible values.

The current position of Transport Canada's Economic Evaluation Branch is that a single value should be used throughout the Department, and that $1.5 million is appropriate.

## 3.5 RECENT FOREIGN PRACTICE

Values for transport safety are used routinely in many countries, particularly in road investment analysis. Recent official values of transport safety were as follows:

| | Approximate $ Can., 1989 |
|---|---|
| United States: | |
| Federal Highway Administration (FHWA)[55] | 2,400,000 |
| Federal Aviation Administration (FAA)[56] | 2,500,000 |
| Department of Transportation (DOT) General Counsel[57] | 1,600,000 |
| United Kingdom[58] | 1,000,000 |
| Australia[59] | 480,000 |
| Germany[60] | 850,000 |
| Finland[61] | 950,000 |
| France[62] | 350,000 |
| Sweden[63] | 950,000 |

Values for road safety in most of the countries have been based on the measurable money losses, due to an admitted inability to reveal values in any other way. This is true in Australia, Germany, France, and, until recently, the United Kingdom. As these losses consist mainly of the earnings expected to be lost over a lifetime, most of the differences among the countries arise through differences in wage rates and discount rates. (Canada's Road Safety values were lower than most because of a higher discount rate.)

The value shown for the United Kingdom was the result of an explicit ministerial decision to nearly double the previous value because it gave insufficient priority in road improvement decisions to safety compared with saving time and operating costs, and therefore favoured proposals that increased road traffic volumes or speeds at the expense of safety.[64] The value has subsequently been argued to represent a reasonable median value from the willingness-to-pay research.[65]

The value shown for the U.S. DOT General Counsel also reflects a political decision in 1986 on the minimum value to be defended in public by that department. It is now superseded at FHWA and FAA by the higher values recently proposed by those agencies, on the basis of a consultant's assessment that the research evidence converges to those values.

# ENDNOTES

1. The term "casualty" refers to either death or injury.

2. "Risk" is used to refer to a **rate** of accidents or casualties per unit of traffic (for example, vehicles, veh-km or pass-km).

3. Total car/light-truck highway traffic is estimated at 210 billion pass-km in 1991. Transferring 1% of that, or 2.1 billion pass-km, with an average risk of 13 deaths per billion pass-km would save about 27 road deaths, while if it achieved the average risk for Levels 1 and 2 air carriers combined, of 0.13 deaths per billion pass-km, expected aviation deaths would rise by only 0.27.

4. A particularly interesting recent comparison of risks between road and air suggests that a typical U.S. business traveller who is sober, in a large car, in daylight, on limited-access highways faces a **lower** risk than on a scheduled flight for distances up to 1 000 km! (L. Evans, M.C. Frick and R.C. Schwing, "Is it safer to fly or drive?," *Risk Analysis* 10(2) (1990), pp. 239–246).

5. Passenger-kilometres reported by Statistics Canada are for carriers of Levels 1 to 4, so this 3.5% share actually represents carriers of Levels 3 and 4, rather than 3 to 6. However, it is expected that the passenger traffic carried by Levels 5 and 6 is so small as to be almost negligible in the total for Levels 3 to 6, and in the estimation of fatality rates per pass-km for this class of carriers. In support of that contention, it can be noted that prior to 1981, Statistics Canada reported pass-km for Level 5 carriers on unit toll services, and that, in 1980, those carriers provided less than 0.7% of the pass-km reported on services by carriers of Levels 3 and 4, and that the proportion had declined substantially since 1976 (Statistics Canada, *Air Carrier Operations in Canada*, Catalogue No. 51-002, 1975–1981 issues, Table 1 or 1.2).

6. Personal communication between a Transportation Safety Board official and Royal Commission staff.

7. The crash of a Nationair aircraft in Jeddah in 1991, which claimed 261 lives, will substantially change the long-term fatality rates estimated for Canadian carriers as a whole, and that for the Level 2 carriers quite dramatically. The 10-year average passenger fatality rate per billion pass-km for Level 2 carriers will rise from 0.7 to about 4.6, and the combined rate for Levels 1 and 2 from about 0.1 to 0.6.

17. Problems of interpretation mean that it is possible that some intercity bus accidents and their victims were not identified.

18. As noted in Volume 1, Chapter 13, these ferries comprise the marine ferries on the west and east coasts, together with the crossings of the St. Lawrence tidal estuary in Quebec, and the Tobermory-South Baymouth service in Lake Huron.

19. Personal communication from Transportation Safety Board staff to Royal Commission staff, Dec. 2, 1991.

20. It is not possible from the available evidence to observe whether the annual fatalities were changing through the decade. Ferry traffic (measured by number of passengers carried) grew substantially through the decade, but no equivalent growth in fatalities can be seen in Table 8(2)-14.

21. P. Gutoskie, *Road Accident Statistics in Canada — 1989*, Report TP 10812, Road Safety Directorate (Ottawa: Transport Canada, March 1991), Table A14. The subsequent publication for 1990 records the number of "rural" fatalities as 2,654 (TP 11230, Jan. 1992).

22. Royal Commission staff estimate, based on 420,000 heavy trucks assumed in use in 1989, and kilometres per vehicle as estimated in F. Nix, M. Boucher and B. Hutchinson, "Road Costs," in Volume 4 of this report.

23. Note that Nix et al. estimate that heavy trucks travel some 2.5 times as many kilometres per vehicle per year as cars and light trucks (44,000 compared with 17,600), in which case their rate of fatal accident involvement per vehicle-kilometre can be inferred to be only 40% of that for cars and light trucks (or 1 ÷ 2.5).

4.2 Surface Modes 314

ENDNOTES 316

# INTRODUCTION

These notes provide background information on the accessibility of transportation to people with disabilities. The topics covered include:

1. the current legislative base;
2. National Transportation Agency orders and regulations;
3. major events, studies and inquiries; and
4. a comparison of U.S. and Canadian legislation and regulations designed to improve transportation accessibility.

# 1. LEGISLATIVE BASE

Early in Chapter 9, Volume 1, the current situation relating to Canadians with transportation-relevant disabilities is described. One key to understanding this situation is a knowledge of the legislation that provides the principles to be observed in improving access to transportation services for travellers with disabilities. This section quotes these legislative provisions and briefly describes how they interrelate.

## 1.1. THE *NATIONAL TRANSPORTATION ACT, 1987*

The *National Transportation Act, 1987*[1] (NTA, 1987) applies to all federally regulated modes of transportation. For passenger services this includes all air, most rail, and some bus and marine services. Paragraph 3(1)(g) of the Act provides that:

> each carrier or mode of transportation, so far as practicable, carries traffic to or from any point in Canada under fares, rates and conditions that do not constitute . . . an undue obstacle to the mobility of persons, including those persons who are disabled. . . .

The NTA, 1987 also provides direction to the National Transportation Agency concerning its specific role in improving access to transportation services for people with disabilities. This direction took effect through the July 1988 amendments to the Act that read as follows:

> 63.1(1) The [National Transportation] Agency may, with the approval of the Governor in Council, make regulations for the purpose of eliminating undue obstacles in the transportation network governed by this Act to the mobility of disabled persons, including regulations respecting
>
> (a) the design, construction or modification of, and the posting of signs on, in or around, means of transportation and related facilities and premises, including equipment used in them;
>
> (b) the training of personnel employed at or in those facilities or premises or by carriers;
>
> (c) tariffs, rates, fares, charges and terms and conditions of carriage applicable in respect of the transportation of disabled persons or services incidental thereto; and
>
> (d) the communication of information to disabled persons.
>
> (2) Regulations made under subsection (1) incorporating standards or enactments by reference may incorporate them as amended from time to time.
>
> (3) The Agency may, with the approval of the Governor in Council, make orders exempting specified persons, means of transportation, services or related facilities and premises from the application of regulations made under subsection (1).

63.2 The Agency and the Canadian Human Rights Commission shall co-ordinate their activities in relation to the transportation of disabled persons in order to foster complementary policies and practices and to avoid jurisdictional conflicts.

63.3(1) The Agency may, of its own motion or on application, inquire into a matter in relation to which a regulation could be made under subsection 63.1(1), regardless of whether such a regulation has been made, in order to determine whether there is an undue obstacle to the mobility of disabled persons.

(2) Where the Agency is satisfied that regulations made under subsection 63.1(1) that are applicable in relation to a matter have been complied with or have not been contravened, the Agency shall determine that there is no undue obstacle to the mobility of disabled persons.

(3) On determining that there is an undue obstacle to the mobility of disabled persons, the Agency may order the taking of appropriate corrective measures, or the payment of compensation for any expense incurred by a disabled person arising out of the undue obstacle, or both.

On June 18, 1992, an omnibus Bill (C-78) was passed by Parliament. It amended six Acts, including section 3 of the NTA, 1987. The words "accessible" and "persons with disabilities" were added to the introductory statement of section 3, which is the key statement of general policy in the Act. The statement now reads as follows:

> It is hereby declared that a safe, economic, efficient, and adequate network of viable and effective transportation services accessible to persons with disabilities . . . is essential to serve the transportation needs of shippers and travellers, including persons with disabilities. . . . [addition underlined]

## 1.2 THE *CANADIAN CHARTER OF RIGHTS AND FREEDOMS* AND THE *CANADIAN HUMAN RIGHTS ACT*

Section 63.2 of the NTA, 1987, directs the National Transportation Agency to coordinate its efforts on behalf of persons with disabilities with the efforts of the Canadian Human Rights Commission. In questions relating to persons with disabilities, the judicial system, including the Canadian Human Rights Commission, is influenced by the equity provisions of the *Canadian Charter of Rights and Freedoms*[2] and the *Canadian Human Rights Act*.[3] The key section of the Charter reads:

> *Equality Rights*
>
> 15.(1) Every individual is equal before and under the law and has the right to the equal protection and equal benefit of the law without discrimination and, in particular, without discrimination based on race, national or ethnic origin, colour, religion, sex, age or mental or physical disability.
>
> (2) Subsection (1) does not preclude any law, program or activity that has as its object the amelioration of conditions of disadvantaged individuals or groups including those that are disadvantaged because of race, national or ethnic origin, colour, religion, sex, age or mental or physical disability.

The key sections of the *Canadian Human Rights Act* stipulate:

> *General*
>
> 3.(1) For all purposes of this Act, race, national or ethnic origin, colour, religion, age, sex, marital status, family status, disability and conviction for which a pardon has been granted are prohibited grounds of discrimination.
>
> (2) Where the ground of discrimination is pregnancy or child-birth, the discrimination shall be deemed to be on the ground of sex.

*Discriminatory Practices*

5. It is a discriminatory practice in the provision of goods, services, facilities or accommodation customarily available to the general public

   (a) to deny, or to deny access to, any such good, service, facility or accommodation to any individual, or

   (b) to differentiate adversely in relation to any individual,

   on a prohibited ground of discrimination.

### 1.3 HOW THE SYSTEM WORKS

Although subsection 63.3(1) of the NTA, 1987 gives the National Transportation Agency the power to initiate inquiries into matters that relate to a regulation or a potential regulation, until recently the Agency normally limited its activities to the investigation of possible undue obstacles. In these cases, an individual had to have experienced an unsatisfactory situation before registering a complaint.

Under the *Canadian Charter of Rights and Freedoms* and the *Canadian Human Rights Act*, a traveller with a disability must have attempted to travel and been denied access in order to have a case. As pointed out in Chapter 9 of Volume 1 of this report, it is not sufficient to know that one would be refused access to a mode of transportation — a person must have been denied access before having recourse to the Canadian Human Rights Commission.

## 2. NATIONAL TRANSPORTATION AGENCY ORDERS AND REGULATIONS

This section outlines the key initiatives undertaken by the National Transportation Agency to improve the accessibility of transportation for people with disabilities. Since the NTA, 1987 was amended in July 1988, the Agency has resolved over 50 complaints about possible undue obstacles and has initiated four inquiries.

## 2.1 ORDERS AND DECISIONS

In response to complaints lodged with the National Transportation Agency, the Agency issued several orders and decisions to improve accessibility. For example:

- Canadian Partner (Ontario Express Ltd.) was ordered to reverse its policy of refusing to carry certain persons with disabilities on small aircraft (September 1990).
- Air Canada was instructed to make wheelchairs available on all aircraft that are equipped to store them and to assist those people who require help in using the nearest on-board washroom (July 1991).
- McIntosh Limousine Service at Lester B. Pearson International Airport in Toronto was ordered to provide transportation to all passengers with disabilities and to inform all of its drivers of this policy (August 1991).
- In June 1991, Air Canada and Canadian Airlines International were ordered to provide a reasonable number of copies of their safety briefing material in both braille and large print, in addition to the personal safety briefing provided to passengers with visual disabilities, effective August 1, 1992. The carriers were further required to show why they should not also provide safety information on audio cassettes. The Agency accepted the carriers' arguments that it is not operationally possible to provide such information on audio cassettes at this time.

## 2.2 REGULATIONS

On March 21, 1992, the National Transportation Agency published proposed regulations regarding transportation access for persons with disabilities in the *Canada Gazette, Part I*. The final regulations are proposed to become effective one year after they have been published in the *Canada Gazette, Part II.* As of July 31, 1992, they had not been published in Part II. The proposed regulations comprise two components:

- amendments to the *Air Transportation Regulations* "to regulate the domestic carriage of persons with disabilities in aircraft of 30 or more passenger seats relating to services to be provided to persons with disabilities;" and
- Personnel Training Regulations for the Assistance of Disabled Persons, which would apply to personnel in the transportation network governed by the *National Transportation Act, 1987* (all domestic air, rail, marine passenger carriers and Newfoundland's Roadcruiser bus service).

### 2.2.1 *Air Transportation Regulations* — Amendment

The proposed amendments to the *Air Transportation Regulations* specify, step by step, the kinds of assistance that must be provided to travellers with disabilities from the time they register at the check-in counter until they enter the general public area after retrieving checked baggage. The amendments also specify the way to handle special aids, such as wheelchairs, that are required for the mobility and well-being of a traveller.

Although these regulations in general apply to aircraft with 30 or more passenger seats, if an aircraft has fewer than 60 passenger seats, and its design prevents carrying an electric or manually operated wheelchair or three-wheel scooter, the air carrier is not required to carry the special aid. The air carrier, however, must advise the traveller about transportation arrangements that are available for the aid.

Where there is a conflict between the proposed regulations and any safety regulations made under the *Aeronautics Act*, the latter prevail.

The description of the proposed regulations indicates that they address areas agreed upon by organizations representing people with disabilities and air carriers. An important feature of the regulations is the guarantee of uniformity of services throughout the country for travellers with disabilities.

The description also acknowledges that the largest impact upon carriers will be on the small and medium-sized operators (about 25 in Canada) that will need to establish comprehensive programs for responding to people with disabilities. The regulations, however, do not require alterations to transportation equipment. Because the amendments apply only to procedures, the description states that "it is not anticipated that carriers will incur additional operating expenses."

The National Transportation Agency also noted in its general description of the regulations that the original set of proposals sent to interested parties in July 1988 "also referred to special air fares for the assistants of passengers with disabilities, and for additional seats required to accommodate a disability. The section on special air fares has been removed to permit further consultation."

In Chapter 9 of Volume 1 of this report, the Royal Commission recommends that:

> When the National Transportation Agency or the carrier concludes that, for safety reasons, an attendant is needed during a trip to assist an individual with a disability, the attendant's fare be borne by the carrier. Otherwise, the traveller should bear the cost. To ensure consistency, carriers should coordinate their policies in this area.
> (Recommendation 9.8)

Section 154 of the Agency's proposed regulations states that "an air carrier shall accept the determination made by or on behalf of a person that the person does not require any extraordinary service during a flight." "Extraordinary service" is defined as "any service related to a disability that is not required by [the proposed regulations] to be provided by an air carrier or any service that is not normally provided by an air carrier."

### 2.2.2 Personnel Training Regulations

This set of regulations applies to personnel employed by carriers in all modes of transportation and by owners, operators and lessees of passenger transportation networks governed by the Act, every operator of a terminal, including personnel, and agents who provide transportation-related services such as security, parking, car rentals, baggage handling and, in the case of air travel, ground transportation from the terminals. Exempt from the regulations are small air carriers whose gross annual revenues are less than $250,000 or whose operations are limited solely to serving the needs of a lodge operation, and owners, operators or lessees of air terminals where less than 10,000 passengers were enplaned and deplaned during the preceding year.

The definition of "carrier" used in the proposed regulations restricts the application of the regulations to Canadian citizens or permanent residents and governments in Canada or their agents. It also applies to any entity that is controlled in fact by Canadians having at least 75 percent of the voting interests, and that operates a passenger transportation service within and from Canada.

As with the amendments to the *Air Transportation Regulations*, the Agency is aiming for uniform training standards across the country so travellers with disabilities will know what to expect during any Canadian trip. Essentially, the training of carrier personnel is to be at a level appropriate for the requirements of their jobs and should emphasize:

(a) knowledge of the policies and procedures of the carrier and operator with respect to a person with a disability, including relevant regulatory requirements;

(b) recognizing those disabilities most likely to need special services, and knowing the responsibilities on the part of the carrier and operator in relation to those disabilities, such as the level of assistance, methods of communication, and aids or devices generally required by a person with a disability; and

(c) acquiring the necessary skills to assist a person with a disability, by knowing the role of the assistant as well as the needs of a person travelling with a service-animal, including the role and the needs of that animal.

In addition, applicable carrier personnel are to be trained in the areas of providing physical assistance to passengers with disabilities and handling mobility aids (including disassembling and assembling) and special equipment.

Carriers and terminal operators are required to file a description of their training programs, in a form set out in the schedule included in the regulations. This description must be filed with the Agency when the regulations come into force, that is, one year after their publication in Part II of the *Canada Gazette*.

Because the Agency's proposed training regulations are not yet in effect, the Royal Commission recommends in Chapter 9 of Volume 1 that:

> Carriers ensure that personnel who are in a position to assist travellers with disabilities be trained to deal with such passengers with sensitivity and understanding.
> (Recommendation 9.9)

## 2.3 OTHER PROPOSED REGULATORY INITIATIVES OF THE AGENCY[4]

### 2.3.1 Special Air Fare Policy

At the same time that the Agency prepared the proposed revisions to the *Air Transportation Regulations* discussed earlier, it also developed a special air fare policy. The regulations relating to this policy for aircraft with 30 or more seats have been separated from the other air regulations, and additional consultations are being held with the Air Transport Association of Canada, and with groups representing people with disabilities. It should be noted, however, that in approving draft regulations the Agency has determined that it is an undue obstacle to the mobility of people with disabilities to charge for the seat used by an attendant needed to provide services additional to those provided by the carrier, or to charge for additional seating that is needed to accommodate the passenger because of a disability. The current expectation is that the proposed regulations on special fares will be submitted to the Minister of Transport in autumn 1992.

### 2.3.2 Terms and Conditions of Carriage in Small Aircraft

Agency staff is currently completing an inquiry report into the manner in which carriers operating small aircraft serve people with disabilities. The report is expected to make recommendations on proposed regulations and will be provided to the industry for comment. The regulations will be for small aircraft (under 30 seats) and will cover services, fares for attendants, and fares for additional seats required to accommodate a passenger because of a disability. The Agency is expected to submit the regulations to the Minister early in 1993.

### 2.3.3 Terms and Conditions of Carriage in Other Federal Modes of Transportation

These proposed regulations will standardize the services provided to passengers with disabilities in modes of transportation (other than air) that are under federal jurisdiction. The proposals are being developed in consultation with an advisory committee representing people with disabilities, industry and federal government departments, including Transport Canada. The regulations are expected to be submitted to the Minister late in 1992.

### 2.3.4 Multimodal Equipment Accessibility

The proposed regulations will cover accessibility features in transportation equipment for all modes of transportation under federal jurisdiction. As for regulations concerning the terms and conditions of carriage, these proposals are being developed in consultation with an advisory committee representing all of the relevant parties. Two inquiries — one on ferries, the other on extra-provincial motor coaches — are currently under way and their results will be taken into consideration in the redrafting of the equipment standards. When these standards are amended, they will be distributed to the advisory committee members for comment before being submitted for Agency approval. The proposed regulations (with the exception of ones dealing with extra-provincial motor coaches) will be submitted to the Minister of Transport at the end of 1992.

### 2.3.5 Communication of Information to People with Disabilities

This initiative is expected to standardize, in all transportation modes under federal jurisdiction, the way information is provided to people with sensory or cognitive impairments. Agency personnel are currently developing draft regulations for consideration within the Agency. It is expected that these will be submitted to the Minister of Transport during the summer of 1993.

### 2.3.6 Accessibility of Transportation Facilities (Terminals)

Agency staff are currently considering draft standards developed by Transport Canada, as well as the Canadian Standards Association Barrier-Free Design Standards, to determine how they can be incorporated into a regulatory proposal covering terminals in all modes under federal jurisdiction. It is expected that the proposal will be submitted to the Minister of Transport during the fall of 1993.

## 3. MAJOR EVENTS, STUDIES AND INQUIRIES

The following section presents further details on major developments relating to transportation accessibility.

### 3.1 INDEPENDENCE '92

This major international conference was held in Vancouver from April 22 to 25, 1992. Its theme was "Self-Determination by Persons with Disabilities." The conference included an exposition whose centrepiece was "Independence Street," featuring an accessible bus as well as buildings and sidewalks that were designed to be very accessible. The conference concluded the United Nations Decade of Disabled Persons, giving people with disabilities and their representatives the opportunity to celebrate the accomplishments of the past decade and prepare for future initiatives.

## 3.2 CANADA COACH LINES DEMONSTRATION PROJECT[5]

A major demonstration project of accessible intercity busing commenced in October 1989 in the Kitchener to Niagara Falls corridor in Ontario. Although some experience in providing intercity accessible bus transportation had been gained in Newfoundland since 1985, an additional demonstration project was required to assess the demand for accessible intercity bus service and to collect information concerning the economics of such a service.

Canada Coach Lines (CCL) was the only bus company that expressed an interest in offering such a service and, therefore, was awarded a contract by Transport Canada for the demonstration project.

The service is scheduled to continue for three years. It operates in a 180-kilometre corridor from Kitchener to Cambridge, Hamilton, St. Catharines and Niagara Falls serving a population of approximately 900,000. Within this corridor, more than 13,600 people with disabilities had registered to use the local para-transit service. These registrants made up the minimum potential market for the demonstration project.

All scheduled services within the corridor are provided by accessible buses that have the capacity to carry two passengers in wheelchairs. Although not a requirement, passengers are encouraged to reserve their trips in advance to ensure that space is available. Reservations can be made from anywhere in the corridor by means of a toll-free number.

### 3.2.1 Key Results of the First 21 Months

*Users:* When surveyed, travellers with disabilities who used the intercity bus expressed a high level of satisfaction with the service. All users stated that they would continue to use the service. Two thirds said that they had taken more intercity trips because the service was available and a quarter said that they would not have travelled otherwise.

The total usage of the service, however, was very low. During the first 21 months, only 242 trips were made by people with disabilities, an average 12 trips per month. Only 41 people used the service, and two of these made 47 percent of all the trips. Thus, only about 0.3 percent of the potential market took advantage of the service, and the trips made by people with disabilities represented only approximately 0.04 percent of the total trips taken.

*Operations:* The accessible service has had little effect on CCL's operations. Because the number of disabled travellers has been relatively low, the additional effort required to book reservations and to coordinate transfers and other activities has not placed a significant burden on the operations staff. During the first 21 months, there were only 13 incidents that affected the operation of the service and none of these was major.

*CCL Personnel:* Canada Coach Lines developed a one-day training program for the personnel who would be serving passengers with disabilities. In a September 1990 survey of drivers and dispatchers, 90 percent stated that they believed they had been adequately trained. Four drivers indicated that they had experienced some difficulty in understanding some passengers' speech, which might suggest that future training should include techniques for dealing with the problem.

*Vehicles:* During the first 21 months, the lifts on the buses malfunctioned 26 times — resulting in minor delays, but all passengers were carried safely. It was found that the accessible buses require a higher level of maintenance than similar non-accessible buses. This is due mainly to the specialized equipment, especially the lift, as well as to increased brake wear, apparently caused by the weight of the lift and additional equipment. During the first year of the demonstration, maintenance costs averaged 7 cents per kilometre for the accessible coaches, compared with 2.5 cents for the non-accessible coaches. However, maintenance costs were highest during the first six months and have since decreased.

*Marketing:* When the demonstration project was initiated, major promotional efforts were made to inform potential customers of the existence of the service. Despite these activities, the service has not achieved a high level of market penetration. Brochures distributed through consumer organizations and local para-transit services appear to be the most effective way to inform potential users about the service.

*Financial Data:* During the first 21 months, the total cost of the demonstration was $338,800, of which $240,000 came from Transport Canada, $1,250 came from travellers with disabilities, and the remainder from Canada Coach Lines. Transport Canada paid for the lifts, the Washington transfer chairs and a portion of the marketing costs. CCL covered the toll-free telephone line, the personnel training costs, maintenance, and a portion of the marketing costs.

### 3.2.2 Supplementary Comments

In their submissions to the Royal Commission, some groups representing people with disabilities criticized the choice of location for the demonstration project, suggesting that Toronto should have been included. While use by people with disabilities has not been very high, Transport Canada has indicated that the route used for the demonstration is fairly representative of many routes in Canada. In addition, Canada Coach Lines is not licensed to operate into or out of Toronto.

## 3.3 INTERIM REPORT OF THE INQUIRY INTO LEVEL OF ACCESSIBILITY OF FERRY SERVICES

On March 19, 1991, the National Transportation Agency appointed three of its officers to "inquire into . . . whether the equipment and services offered by ferry companies under federal jurisdiction constitute undue obstacles to the mobility of persons with disabilities and make recommendations for the removal of such undue obstacles as they may discover."[6] These officers contacted major associations of, and for, people with disabilities, ferry operators, and provincial and federal governments. They met with representatives of many of these organizations and inquired into difficulties in gaining access to the vessels, accessibility to services on vessels, the awareness and training of ferry personnel, aspects of carriers' fare policies governing travellers with disabilities and the costs of providing accessibility. The inquiry officers also made their own examinations of some frequently used services.

Among the ferry services visited were BC Ferries (Canada's largest ferry operator but provincially regulated since it operates within British Columbia), Marine Atlantic Inc., Northumberland Ferries Limited, Société des traversiers du Québec and Coopérative de transport maritime et aérien (CTMA). The inquiry team also held discussions with providers of provincial services in Newfoundland and British Columbia.

The inquiry reached the following conclusions[7] in its interim report dated January 17, 1992:

1. Overall, carriers are making efforts to improve accessibility; Marine Atlantic especially is making efforts and in doing so benefits from its on-going consultations with an Advisory Accessibility Committee.

2. There are no national standards across Canada and the inquiry officers believe that inconsistencies in levels of accessibility pose obstacles to the mobility of persons with disabilities.

3. Since Northumberland Ferries Ltd. is reliant upon the federal government, through Transport Canada, for its operations, the inquiry officers believe that its operations should reflect the policy of the federal government. Transport Canada is a participating Department in the National Strategy for the Integration of Persons with Disabilities, whose purpose is to encourage industry to develop and use equipment that will advance accessibility of transportation.

The inquiry's interim report was circulated to interested parties, and comments were received and analyzed. The Agency has noted the findings in their Final Report, which will also be distributed to interested parties. That part of the report dealing with proposed regulations will be incorporated into the Agency's regulation development program.

## 3.4 INQUIRY INTO CANADIAN MOTOR COACH SERVICES

This inquiry, entitled "The Road to Accessibility," is examining the level and adequacy of accessible services currently available on extra-provincial motor coaches. The inquiry is also to determine if it is appropriate to set a national standard for services, and the financial implications of doing this. Public hearings are being conducted throughout the country and it is expected that a report will be presented to the Minister of Transport early in 1993.

## 3.5 INQUIRY INTO GROUND SERVICES AT AIRPORTS

In response to a request from the Canadian Paraplegic Association, the Agency is inquiring into whether the equipment and services offered by automobile rental agencies, taxis, limousines and airport shuttle buses operating at or from Canadian airports present undue obstacles to the mobility of people with disabilities. At the time of writing, it is expected that the inquiry will be completed in the summer of 1992.

### 3.6 INQUIRY INTO THE POLICIES OF CANADIAN AIR CARRIERS

This inquiry into the policies, standards and practices of all Canadian air carriers with respect to transporting people with disabilities was conducted in two parts. The first part dealt with operators of large aircraft (30 seats or more) and has been circulated to interested parties; the second dealt with the accessibility of smaller aircraft (fewer than 30 seats) and should be circulated to interested parties in late 1992.

## 4. A CANADA–UNITED STATES COMPARISON

Chapter 9 of Volume 1 describes the frustration and progress that has occurred in relation to access to transportation for people with disabilities. It specifically mentions the *Americans with Disabilities Act of 1990,* a major event in the United States. This section describes the U.S. legislation and compares it with the situation in Canada.

Canada has not been alone in becoming more aware of the needs of people with disabilities. As is noted in Volume 1, Chapter 9, there has been frustration in Canada at the lack of progress in addressing these needs, including increasing access to transportation services. On the other hand, there has been progress in all passenger modes and it would be inaccurate to underrate the importance of the improvements that have occurred. The bus mode appears to have improved most slowly and, therefore, it is especially positive that the National Transportation Agency embarked on a major inquiry into accessibility within this mode.

In Canada, progress toward increased accessibility has been uneven. This is also the case in other countries that the Royal Commission examined. The example of the United States has been of particular interest to Canadian organizations of and for persons with disabilities, because of the passage of the *Americans with Disabilities Act of 1990,* which applies to the rail and bus modes, and the *Code of Federal Regulations* pursuant to the *Air Carrier Access Act of 1986,* which applies to the air mode. Some Canadian organizations would argue that this legislation places the United States well ahead of Canada in its treatment of people with disabilities. The provisions in the Code and the Act are very comprehensive. In addition, the Act provides for new regulations regarding standards to be met. The following provides a summary of some of the major provisions.

## 4.1 AIR MODE

The *Code of Federal Regulations* puts into practice the *Air Carrier Access Act of 1986*, which states that, when providing air transportation, no air carrier may discriminate against any otherwise qualified person because of a disability.

The Act and the Regulations specify in considerable detail how aircraft and their interiors must be configured to make seats and washrooms accessible; how airport facilities should be designed; when an air carrier is required to provide transportation to a person with a disability and to provide the services that make the trip feasible (such as oxygen); how aircraft boarding and seat selection are to be performed; when and how personal equipment such as wheelchairs and other aids are to be stowed; how information must be provided to travellers with disabilities; and what special services must be available to people with hearing impairments.

The key provisions on arrangements for attendants accompanying travellers with disabilities are as follows:

- A carrier may require that an attendant accompany a person with a disability in specific circumstances for the safety of the passenger (for example, if a mental disability or severe hearing and sight disabilities prevent the passenger from understanding the safety briefing).
- If the carrier determines that a passenger must travel with an attendant, but the passenger believes that he or she is capable of travelling independently, the carrier shall not charge for transporting the attendant.

- If the carrier determines that an attendant is necessary but an extra seat is not available on the flight on which the traveller has a confirmed reservation, then the traveller with the disability shall be eligible for denied-boarding compensation.

As described earlier in Section 2 of these Notes, the National Transportation Agency has proposed regulations regarding accessible transportation, which will become effective one year after the date of their publication in the *Canada Gazette, Part II.* At the time of writing, the publication in Part II had not occurred. One important consideration to organizations of, and for, persons with disabilities relates to fares for attendants. This issue has not been covered in the regulations the Agency has promulgated to date. The Royal Commission's recommendation concerning attendants is similar to the U.S. requirement already in place.

In the United States, if the physical limitations of an aircraft with less than 30 passenger seats preclude the use of existing models of lifts, boarding chairs or other feasible devices to enplane a person with a disability, air-carrier personnel are not required to carry that person onto the aircraft by hand. In Canada, the currently proposed amendments to the regulations do not pertain to aircraft with fewer than 30 seats. Consequently, there are no regulations available at present to compare with those in the United States. A specific National Transportation Agency decision, however, suggests a direction for the Canadian situation. For example, the Agency ordered Canadian Partner (Ontario Express Ltd.) to make its transportation system accessible to persons with disabilities. This case involved a Jetstream 31 aircraft, which has 19 seats. In response, Canadian Partner is exploring, with manufacturers, the development of a device that will allow access to aircraft in a dignified manner by passengers requiring assistance. However, until a suitable device is available, passengers requiring assistance in ascending and descending stairs on the Jetstream 31 will be manually lifted by Canadian Partner crew. Training in various lifting techniques will be provided to the personnel involved.

In Canada, as described earlier, the National Transportation Agency has proposed regulations for domestic air carriers using aircraft with 30 or more seats. At the present time, Air Canada and Canadian Airlines International each have various special services, not currently required by regulation, to assist travellers with disabilities. These special services are similar to some of the provisions found in the *Code of Federal Regulations* for U.S. air carriers and include:

- advance seat selection;
- a toll-free line available in Canada for those with a Telecommunications Device for the Deaf (TDD);
- reduced fares for attendants on flights within North America;[8]
- transportation of wheelchairs free of charge in the cargo compartment and the provision of special packing for wet-cell battery packs used on motorized chairs;
- for in-flight use, airline-provided wheelchairs on all airplanes except DC-9s and Boeing 747 combis (Air Canada) and Boeing 737s and DC-10s (Canadian Airlines International);
- on all Boeing 727s, 767s and 747s (Canadian Airlines International only for the latter), Airbus A310s and A320s, and DC-10s,[9] washrooms that are accessible to passengers in wheelchairs;
- on all aircraft, except Air Canada's Boeing 747 combis and some 727s, retractable arm rests on selected aisle seats to ease the transfer of travellers from wheelchairs to their seats;
- oxygen "Medipaks," for passengers with respiratory problems, available at an extra charge with advance notice (72 hours for Air Canada and 24 hours for Canadian Airlines International);
- provision for guide dogs accompanying passengers with a visual or hearing impairment in the passenger cabin, except on flights to the United Kingdom and New Zealand, due to animal quarantine regulations in those countries;

- a variety of specially prepared meals when advised 24 hours in advance;
- individual on-board safety briefings; and
- a special facility at Lester B. Pearson International Airport with full-time airline staff offering assistance to passengers needing boarding assistance (Air Canada at Terminal 2 and Canadian Airlines International at Terminal 3).

## 4.2 SURFACE MODES

The *Americans with Disabilities Act of 1990* provides the criteria to determine if discrimination under the Act has occurred in providing transportation services to people with disabilities. Separate criteria are set out for:

- public entities such as bus, rail, or any other conveyance (other than aircraft or intercity or commuter rail) that provide the general public with general or special service (including charter service) on a regular and continuing system;
- operators of commuter rail transportation and intercity rail transportation (the latter being Amtrak); and
- private entities offering travel or transportation services. (These services include transportation by bus, rail, or any other conveyance, other than by aircraft, that provides the general public with service, including charter, on a regular and continuing basis.)

For the most part, there are differences between new and existing equipment and facilities. Generally speaking, new equipment must be accessible to travellers with disabilities. Private entities, however, operating purchased or leased vehicles with a seating capacity of fewer than 16 passengers face more relaxed requirements. Existing equipment and facilities must be fully accessible by specified deadlines.

One controversial area relating to the application of the Act and Regulations concerns over-the-road buses.[10] To deal with these issues, the Office of Technology Assessment has undertaken a study to determine:

- the access needs of individuals with disabilities to over-the-road buses and over-the-road bus service; and
- through consideration of all forms of boarding options, the most cost-effective methods for providing access to over-the-road buses and over-the-road bus service to individuals with disabilities, particularly individuals who use wheelchairs.

The study, including any options for legislative action, is to be submitted to the President and Congress by July 1993.

In Canada, for the surface modes, the major event related to accessibility is the proposed National Transportation Agency regulations relating to the training of carrier personnel to assist travellers with disabilities. As mentioned earlier in these Notes to Chapter 9, the Agency is in the process of preparing regulations concerning the terms and conditions for transporting persons with disabilities using federally regulated modes other than air (which has already received some attention). Regulations covering the accessibility features of transportation equipment in all modes of transportation under federal jurisdiction are also being prepared, as are regulations to standardize the communication of information to persons with sensory or cognitive impairments.

# ENDNOTES

1. *National Transportation Act, 1987.* R.S.C. 1985, c.28 (3rd Supp.).

2. *Canadian Charter of Rights and Freedoms.* R.S.C. 1985, Appendix II, No. 44.

3. *Canadian Human Rights Act.* R.S.C. 1985, c.H-6 (2nd Supplement).

4. National Transportation Agency of Canada, *Accessible Transportation Services for Persons with Disabilities.* A Staff Report to the National Transportation Act Review Commission, May 1992.

5. *Canada Coach Lines Accessible Intercity Bus Service Demonstration, Preliminary Results* prepared by Transport Canada, Policy and Coordination, Transportation Development Centre, October 1991. Information on the total ridership, potential market of persons with disabilities and allocation of costs between Transport Canada and Canada Coach Lines was obtained from Transport Canada officials.

6. Kenneth A. Mozersky, Anne M. Hampel and Paul Lacoste, *Interim Report of the Inquiry into Level of Accessibility of Ferry Services* (Ottawa: National Transportation Agency of Canada, January 17, 1992.)

7. Ibid., p. 12.

8. The attendant's fare is 50 percent of the applicable fare (whether full or discount) at the time.

9. The DC-10 washrooms could be considered "not fully" accessible since the door to the washroom cannot be closed. Entry to the washroom is facilitated by a bar and a privacy screen, and the latter conceals the Washington chair and doorway while the washroom is in use. Canadian Airlines International, however, is phasing out its DC-10 aircraft.

10. An "over-the-road" bus is defined in the United States as one that has an elevated passenger deck located over a baggage compartment.

ENDNOTES 334

# INTRODUCTION

Chapter 18 of Volume 1 describes the changes in costs by mode to be expected during the decade from 1991 to 2000 under *Status Quo* (S-Q) and *Directions* (D) conditions. The chapter describes the changes forecast using four trips as illustrations:

- Saskatoon to Halifax
- Toronto to Montreal
- Winnipeg to Churchill
- Halifax to St. John's

Subsequently, the system-wide changes to be expected in each mode are summarized when the total estimated costs for 2000 S-Q and 2000 D are presented in Tables 18-5 and 18-6 of Volume 1.

These notes will reverse this order, describing first the system-wide changes to be expected in each mode, and then offering some details for each of the sample trips where these differ from the system-average changes.

In general, the percentages of change cited here for various factors that differ from 1991 to 2000 S-Q, or between 2000 S-Q and 2000 D, are used in developing our illustrative estimates. They do not always match percentage changes that can be calculated from the tables in Chapter 18. The percentage changes implicit in those tables may differ because rounded numbers and sums of rounded numbers were used in the tables.

# 1. CHANGES EXPECTED FROM 1991 TO 2000 S-Q

## 1.1 CHANGES IN TRAFFIC BY MODE

Simple assumptions are made that, in the absence of the policy changes recommended by the Royal Commission, intercity traffic by mode in passenger-kilometres would grow between 1991 and 2000 by:

| | |
|---|---|
| • Car | 30% |
| • Bus | no change |
| • Airplane (domestic) | 30% |
| • Train | no change |
| • Ferry | 30% |

These are not intended to be accurate forecasts, but merely illustrative of the possibilities, in order to allow the implications of the Royal Commission's recommendations to be explored. Their realism can be judged in light of the following observations about recent changes in traffic by mode:

- On Ontario highways, traffic increased between 1980 and 1989 by 36% measured in vehicle-kilometres by all classes of vehicle (separate estimates for car traffic being unavailable).[1]
- Passenger-kilometres on intercity buses are not available, but between 1980 and 1989, total bus-kilometres on intercity unit toll services fell by 16%, while total passengers carried fell by 47%.[2] It is noted, however, that part of the decline is attributable to the reclassification of GO Transit bus services from intercity to urban transit.
- Passenger-kilometres on domestic unit-toll air carrier services increased by 13% between 1981 and 1990, and by 32% between 1983 and 1990.[3]

- Revenue passenger-kilometres on intercity train services declined 3% between 1980 and 1989, and then, on VIA Rail services (87% of the 1989 total), almost halved in 1990.[4]
- The number of passengers carried on intercity ferries increased between 1980 and 1988 by 39% (46% on west coast ferries and 10.5% on east coast ferries).[5]

## 1.2 CHANGES IN COSTS BY MODE BETWEEN 1991 AND 2000 S-Q

### 1.2.1 Car

The 2000 S-Q case differs from the 1991 case in allowing for some improvements in vehicle fuel consumption, emissions and safety. Fuel efficiency and $CO_2$ emissions are expected by Environment Canada and the National Energy Board to improve by about 13% per vehicle (fleet average) by the year 2000.[6] In the cost estimates, the fuel component of vehicle/carrier costs is therefore reduced by 13% in 2000 S-Q, and the $CO_2$ component of environmental damage costs is reduced by 13%.

The Canadian Council of Ministers of the Environment, through adoption of its Management Plan, intends that $NO_x$ and VOCs emissions will fall by about 40%, including the effects of announced vehicle emission standards and a number of specific programs in the "ozone-sensitive areas."[7] The $NO_x$/VOCs component of environmental damage costs is therefore reduced by 40% in 2000 S-Q.

Safety is predicted to continue to improve in terms of fatality rates per vehicle and per passenger-kilometre; recent trends have been strongly downward, but the longer term reduction is somewhat slower. On the other hand, the frequency of less-severe accidents and their damage costs continue to increase. An expectation that the reduction in deaths will predominate in the cost equations is represented by a reduction of 10% in the cost per passenger-kilometre.

The fuel tax component of special taxes/fees is assumed to be unchanged per passenger-kilometre, despite the reduction in fuel consumption noted earlier. It is expected in the status quo option that governments would adjust tax rates upward to offset reductions in tax revenue per passenger-kilometre (their practice over the last 15 years having been to increase tax rates more than needed to offset reductions in fuel consumption per vehicle-kilometre).

Together, these changes would reduce average car costs per passenger-kilometre by about 4% by the year 2000.

### 1.2.2 Bus

The illustrative figures for the bus mode, projected to 2000 but presuming no change from the present regime of provincially regulated regional monopolies, reflect an expectation that, without major policy change, there will be little improvement in costs in this mode. Only the cost of accidents is projected to fall by 10% per vehicle-kilometre and per passenger-kilometre compared with 1991 — reflecting a continuing trend toward safer travel by improving vehicle technology and improving infrastructure and control systems.

This portrayal of 2000 S-Q bus costs could prove optimistic if the current decline in the use of this mode continues; however, for the system total and for the sample routes selected, continued deterioration has not been assumed.

### 1.2.3 Airplane

The carrier component of air travel costs is expected to continue to fall through 2000 as the older aircraft of existing fleets are replaced by newer airplanes that are fuel efficient, require fewer people in the flight crews, and have lower maintenance costs. New aircraft will reduce the cost of most Canadian domestic air operations. Aging DC-9s, Boeing 727s and early models of the B-737 are being replaced by a new generation of aircraft. These are quieter, can be operated by a cockpit crew of two (instead of three), and are much more economical on fuel.[8]

In some instances, the newer aircraft can accommodate twice the passenger load at the same fuel consumption. For airplanes, such as the Airbus A320 (which is replacing the B-727-200), the same number of passengers are transported at a 40% fuel saving (approximately 150 people in the "all-economy" configuration). A reliable picture of the maintenance costs for the newer aircraft will have to wait until they have aged, but substantial savings are indicated. The following estimated savings were developed using published U.S. airlines' data.[9]

| **SAVINGS: A320 over B-727-200** | |
|---|---|
| Crew | 10% |
| Fuel | 40% |
| Maintenance | 20% |

For illustrative purposes, and based on the above, the air operations cost models were projected to 2000 by adjusting fuel and labour costs. The aggregate effect was cost reductions, for system-average vehicle/carrier costs in the sample routes, of 11.5% to 13.5%. For the system average, the projected 1991 to 2000 cost reduction is approximately 12%. With cleaner engines and this fuel saving, an emissions reduction of 15% was estimated.

Air traffic has, with intermittent corrections, grown steadily over the years. It is reasonable to assume that such growth would generally continue. Transport Canada staff (from their Passenger Origin-Destination Model) provided Royal Commission staff with forecasts of air traffic origin-destination from 1989 to the year 2000.

The model forecasts indicate a growth in domestic airline traffic of 37% from 1989 to 2000. This amounts to approximately 30% for 1991 to 2000.

Although the traffic increase that is forecast would affect the economics of flying, particularly between lower density city pairs, it is not expected to have any important impact on the system-average load factors (presumed to be 67.5% for jet and 56% for commuter turboprop) used in the carrier cost presentation. On the other hand, the impact on the average unit cost for under-utilized airports would be considerable — presuming that traffic increases are not matched with even more investment.

Aviation infrastructure spending is expected to grow much less than traffic, indicating that costs per passenger-kilometre will fall. Costs at Toronto and Vancouver airports are the exceptions; it is assumed that expansion costs at these airports would preclude economies in per-passenger costs. Otherwise, marginal costs for Calgary, Edmonton, Winnipeg, Ottawa, Montreal and Halifax are assumed to be 50% of 1991 average levels, and at smaller airports, zero. Presuming a system-average growth in airport activity (domestic and international combined) of 42% from 1989 to 2000,[10] average airport costs per passenger-kilometre would fall by 17% at the six airports listed earlier, and by 30% at smaller airports.

Air navigation services costs per passenger-kilometre are projected to fall system-wide by an average of 25% by the year 2000. Total land costs remain unchanged, but are averaged over a 30% greater volume of passenger-kilometres. Average costs attributable to land, therefore, fall by about 23% per passenger-kilometre. Overall, infrastructure costs fall by about 22%.

Improvements in average fuel consumption (as mentioned earlier) will continue as older models of aircraft retire and are replaced by more efficient versions. An improvement of 15% between 1991 and 2000 is assumed, producing an equivalent reduction in $CO_2$ and air pollutant emissions damage. In addition, environmental costs are projected to fall as noise costs are presumed to halve, following more extensive adoption of "Stage III" aircraft.

Aircraft fuel tax per passenger-kilometre is projected to decline by 15%, in line with fuel consumption. For cars, where fuel taxes are the main source of government revenue, it is assumed that governments would adjust road fuel tax rates per litre upward to offset declining consumption. For air, no change in fuel tax rates is assumed. Had the assumption been the same as that made for cars, the difference in total costs in the 2000 S-Q case would have been relatively minor.

Airplane accident costs per passenger-kilometre are presumed unchanged.

In sum, domestic air travel costs per passenger-kilometre are projected to fall by about 15% from 1991 to 2000.

### 1.2.4 Train

Improvements in VIA Rail's cost-recovery performance were generally projected, but assumed to be restricted to its higher potential services. For the sample routes considered, no changes in cost and revenue levels were assumed in cost levels prevailing for Winnipeg to Churchill, or the Montreal to Halifax segment of the hypothetical Saskatoon to Halifax rail journey. For the Saskatoon to Toronto link, a large improvement in average passenger revenue was projected — reflecting an increased emphasis on higher-quality and higher-priced, tourist-focussed transcontinental service. Also included are more-modest increases in per passenger infrastructure and train costs — allowance for the net effects of lower passenger-kilometres per car-kilometre, adjusted in the case of train costs for predicted operating economies.

Projected changes for the Toronto to Montreal sample route are more substantial — in keeping with VIA Rail's plans for a faster service using improved equipment, which will garner higher revenues. Per-passenger vehicle/carrier costs are projected to fall from $124 to $106, revenue to improve by $4 and infrastructure charges to increase (by $2) due to higher speeds.

No change is expected in environmental, accident or special tax/fee costs per passenger-kilometre. The projected reductions in vehicle/carrier costs are sufficient to reduce train costs per passenger-kilometre overall by about 4% between 1991 and 2000.

### 1.2.5 Ferry

No change is anticipated in the costs per passenger-kilometre of any of the ferry services. However, system-average vehicle/carrier costs would fall slightly as growth is expected to be more vigorous among the west coast services (40% growth in passenger-kilometres, compared with 10% on east coast services), and those west coast services have much lower costs per passenger-kilometre.

Overall, ferry costs per passenger-kilometre are projected to fall by about 3% between 1991 and 2000.

## 2. CHANGES EXPECTED FROM 2000 S-Q TO 2000 D

### 2.1 CAR

The year 2000 D case essentially involves:

- A large shift in the burden of the infrastructure costs from taxpayers to users;
- Introduction of payments by users for the environmental damage costs to users, offsetting costs borne by others; and
- A transfer to users of that portion of accident costs hitherto borne by others.

Accident cost changes are a simple transfer. We do not assume any further improvement, although the change in responsibility for cost might well be an incentive for improvement. The infrastructure cost changes and environmental cost changes are more complex, and will be described further.

The analysis of 1991 system-average costs suggested that, within car infrastructure costs, the costs of "control" were matched by registration fees, but the remaining costs of the "way" (including capital charges and land costs, as well as pavement wear and maintenance costs) were approximately double the revenues received by governments from special fuel taxes. Infrastructure cost recovery could be achieved by doubling the fuel tax rate. Implementing the Royal Commission's recommendations, however, should lead to the application of more rigorous criteria to expenditure decisions on the road network, slowing expansion relative to traffic growth.

To illustrate the possible consequences, infrastructure costs are assumed to be about 5% lower in the 2000 D case. Presuming that the fuel tax (the dominant element of the 2000 S-Q special transportation tax/fee) was the means of collecting the infrastructure charge, it would only need to be increased by about 90% to cover the comprehensive costs throughout the road network.

It is expected that, at least for the next decade or so, road infrastructure charges would be applied (through fuel taxes) at the same rate network-wide, rather than differing by link. The new average charges would therefore produce large surpluses over costs on the links with dense traffic, particularly expressway-standard highways. The surpluses would be needed to cross subsidize less-travelled routes that continued to under-recover. This is evident in the illustrations for sample routes, all of which (except Winnipeg to Churchill, which has no continuous road link) are on major highway routes, with sufficient road traffic to show surpluses on the new infrastructure charges in the 2000 D case.

The net cost increase to users under the 2000 D scenario from infrastructure, environmental and accident charges, less special taxes, would not add dramatically to fully allocated average costs per trip. As of 2000, it would constitute an 8% increment to the average cost per passenger-kilometre, or per trip. The increment would be, however, a larger portion of the "out-of-pocket" costs perceived by motorists, and would amount to a large percentage increase in the effective cost of fuel consumption. This might be expected to cause appreciable changes of travel behaviour and especially in the type of vehicle purchased. In the 2000 D illustrations, it is assumed that these reactions will produce another 10% reduction in both fuel consumption and emissions.

Overall, car costs per passenger-kilometre fall by about 2%. It should be noted, however, that demand for road travel will also be somewhat dampened through travelling less and switching modes, which is not represented in the tables.

## 2.2 BUS

Regulatory reform, to allow entry to the intercity scheduled bus industry on the basis of "fit, willing and able" criteria, would open the bus industry to competition, and give operators greater commercial freedom. This could induce cost efficiencies and the removal by carriers of internal cross subsidies among routes. Potential efficiencies are illustrated by a 15% reduction in vehicle-carrier costs of the bus services once carriers are free to adjust equipment, schedules and fares to the market, and to withdraw from services where patronage is insufficient.

The analysis of 1991 costs suggested that public infrastructure costs — the allocated costs of the road system, including capital charges and land costs—are almost balanced by the "special taxes/ fees" from buses. Infrastructure costs per bus-kilometre would fall very slightly (about 5%) along with the overall improvement in road infrastructure spending described in the section earlier on car costs. The new infrastructure charges per bus-kilometre would be introduced at levels only slightly higher than those taxes and fees that they replaced. Adjusting for the improvement in average load factor, infrastructure charges per passenger-kilometre would fall further.

User charges would also be instituted for environmental damage costs, transferring the costs from the general public to bus users. These environmental charges would induce bus fuel consumption improvements and emissions reductions, reinforcing reductions arising through more stringent regulations. The scope for additional improvement in bus emissions per vehicle-kilometre appears large relative to that for cars. Compounding this, with a load factor improvement projected for the 2000 D scenario, a reduction of 30% would be a reasonable expectation.

Overall, operating efficiencies and the removal of cross subsidies would mean that costs borne by users would fall by about 11%, even after imposition of the new user-charges. The average full cost of a passenger-kilometre of bus travel would fall by about 15% from the 2000 S-Q scenario.

Bus costs used for the route-specific illustrations are not estimates of actual costs for the routes in question. They are based on adjusting the system-average costs developed (see Notes to Chapter 3 in this volume) for factors specific to the route type. In some cases what they portray may not be accurate. For example, the costs illustrated in the 1991 and 2000 S-Q cases for Halifax to St. John's are not actual costs of the service provided by CN Roadcruiser, but generic costs for similar services provided privately elsewhere. The actual costs are probably substantially higher. For the Newfoundland service, the expectation is that privatization and/or contracting for operation of subsidized services might well reduce costs proportionally more than shown in Table 18-4, which is based on expected changes in system-average costs.

## 2.3 AIRPLANE

No further changes in air carrier unit costs, except for infrastructure and environmental charges, have been assumed to result from the 2000 D scenario.

Applying the disciplines of full cost recovery and user-sensitive management to airport and air traffic control investment and management should result in infrastructure cost reductions. Actual economies from eliminating excess costs would vary widely by site. Cost saving potential in airports is represented by a reduction of 10% in costs per passenger at Toronto and Vancouver airports, 25% at medium-sized airports, and 35% at smaller airports. Special circumstances are illustrated for the Winnipeg to Churchill example, discussed later.

The illustrative cost reduction presumed to be achieved from public utility style management of air navigation services is 25%. Improvement might well exceed that, as illustrated by the success of the Airways Corporation of New Zealand.[11] Infrastructure costs therefore fall by about 18% on average. Carriers and passengers would be charged directly for these infrastructure costs, but with the exception that the smaller airports[12] would retain transitional subsidies, estimated at $40 million in total in 2000.

The federal fuel excise tax would be eliminated, replaced by a charge for environmental damage. This would induce some additional reduction in aircraft emissions through improved technology or operating practices, illustrated as a reduction of 5% in environmental costs per passenger-kilometre.

Overall, air travel costs per passenger-kilometre fall by about 5% compared with 2000 S-Q. User costs per passenger-kilometre increase by about 10%.

### 2.4 TRAIN

Different effects of the 2000 D scenario on rail carrier and infrastructure cost, and consequent changes in service offerings, are illustrated for the Toronto to Montreal and Saskatoon to Halifax examples, and in subsection 2.6 for the Winnipeg to Churchill example.

The 2000 D scenario illustrates a possible niche for rail on the Toronto to Montreal route. One hypothetical niche could, of course, be a Toronto to Montreal high-speed rail system; however, even if a decision to proceed were taken on the completion of present studies, the system would not be operative until well after 2000. The niche for rail assumed under the 2000 S-Q scenario involves a system that is more expensive to the user — much more expensive. In part, this would be due directly to full commercial cost recovery. Also, with its prices rising, the only possible approach would seem to be for rail travel to seek a market by moving "up scale."

Part of the projected price rise to an average Toronto to Montreal fare of $119 by 2000 (still supplemented by a transition subsidy of $21) is attributable to improved speed, comfort and service. It is possible that travellers would be unwilling to pay 22 cents per kilometre (24 cents per kilometre standardized to air distance, rising to 28 cents over about three years as the VIA Rail subsidy completely disappeared in 2003), even for an improved rail service, and the mode would fail to survive in an open market. Such a rail operation would, however, provide a markedly improved service, and fill a niche closer to air travel than to bus travel. It would cost less than 75% (rising to 87% as transitional subsidies are phased out) of the price of air travel, be more comfortable, and require only marginally more — or in some cases less — travel time, depending on exact origins and destinations within the metropolitan regions. The time disadvantage of rail is further diminished if time spent less conveniently (that is, time in taxis or terminals) is weighted more heavily relative to time spent comfortably aboard the train or airplane.

Saskatoon to Halifax by rail would cost the user more than four times the air price, or $1,556 for a trip with three changes of trains and with average accommodation, when the transition process is complete early in the next century. (Declining subsidies would mean that the trip would cost $1,271, or more than three times the price of air, in 2000.) Anyone choosing such a trip at this cost would doubtless want better-than-average accommodation, and would have to pay substantially more. The system-total reduction of rail passenger-kilometres for the 2000 D scenario by half (to 0.7 billion passenger-kilometres) recognizes the likely major effect of increasing costs on rail patronage. Remaining rail service would probably be concentrated on higher-volume routes and some tourist services.

Because the potential for fuel consumption and emissions reductions appears large, especially as part of a process of concentrating services on higher-volume routes, it is illustrated by a 20% reduction in environmental damage costs per passenger-kilometre.

## 2.5 FERRY

Major changes would be introduced to ferry financing, through a phase-down of subsidies over a 10-year period. In the illustrative case it is assumed that, by 2000, this would apply even to the ferry services that are "constitutional" obligations, and that the subsidy would, by 2000, be only about one quarter of its 1991 level. This stimulus, together with the introduction of other management incentives to efficiency (including the ability to contract services in publicly owned ships, and the institution of an advisory panel of users on services and fares), would be expected to reduce costs. In the illustration, it is assumed that costs fall by 20% per passenger-kilometre on the east coast services and by 5% on west coast services (for which average costs per passenger-kilometre are already substantially lower).

Introducing direct charges for environmental damage would prompt reductions in fuel consumption and emissions of about 20%.

There is also scope for reduction in the average costs of the publicly provided infrastructure. Full cost recovery by Transport Canada, together with the creation of a users' advisory body on investments, services and charges, should stimulate efficiencies in provision of the services. This is represented in the illustration by a reduction of 10% in the infrastructure cost per passenger-kilometre.

In summary, costs to users per passenger-kilometre rise by about 40%, while overall comprehensive costs per passenger-kilometre fall by about 9%.

## 2.6 CHURCHILL TO WINNIPEG: AN ILLUSTRATION OF CHANGE

The town of Churchill has approximately 1,200 residents and no road access. Expenditures by "taxpayers" to maintain existing passenger transportation to and from Churchill are very large per trip, and relative to the total population of the area served. A $19.5-million passenger-rail subsidy in 1990 equalled over $16,000 per resident of Churchill; the airport subsidy amounted to another $8,000 — slightly less if the population served using Churchill Airport as an intermediate point is considered. These are large amounts relative to benefits to the residents. Under the 2000 D scenario, air and rail connections would still be provided but at much lower cost to taxpayers.

### 2.6.1 Air

Churchill Airport accounts for a total annual cost attributable to commercial aviation of $9,524,000. Of this, $3,951,000 and $1,368,000 would be required to cover airfield and terminal capital investments respectively. Operating costs, excluding depreciation but including Transport Canada overhead, were $4,234,000 in 1990-91. Thompson, Manitoba, however, has a lower comparable total annual cost (including cost of capital) and lower operating costs, of $2,832,000 and $977,000 respectively — and Thompson handles similar aircraft and three times the passenger traffic of Churchill. Other comparisons with airports handling similar commercial traffic also confirmed that Churchill is over-built for the commercial aviation traffic it handles.

Although some of the airport facilities might be justified on the basis of military use or other benefits, it would seem reasonable to run an airport at Churchill for about 100 to 150 passengers daily at an operating and maintenance cost of the order of $800,000 annually, or $23 per passenger. Under the 2000 D scenario this would occur.

Presuming that the over-building were written off, it remained to estimate necessary sustaining capital. Here, as will be the case with any specific site, the question of the necessity of providing a full-service jet facility arose; a facility for turboprop aircraft was presumed adequate, at an estimated (sustaining) capital charge of $500,000 annually. Thus, including the charge for using Winnipeg, a total airport cost per passenger of $37 would seem reasonable. To this is added $6 for air navigation services, for a total infrastructure cost of $43. The total is still a substantial increase over the $25 that the average passenger would pay under the 2000 S-Q scenario. For illustrative purposes, a transitional subsidy of $9 is shown, with the average passenger paying $34.

### 2.6.2 Rail

Table 18-3 in Volume 1 illustrates, for Churchill to Winnipeg travel, an important aspect of the Royal Commission's recommendations for rail in more remote circumstances — Recommendation 12.5b, that "any subsidized remote access service (regardless of mode) be designed to take passengers out to and bring them in from the closest convenient point where transfer can be made to a commercial unsubsidized carrier." Rail travel (the average of fares for upper and lower berths) from Winnipeg to Churchill presently costs the traveller $229, and would continue to do so under the 2000 S-Q scenario. This is insufficient even to cover the allocated $280 cost for the use of CN's track. Most of the total cost (including a $41 credit for the excess of attributable fuel taxes over the normal sales tax[13]) of $2,978 per passenger is paid by the taxpayer. No improvement in this cost recovery is predicted unless there is a major change in the service offered.

### 2.6.3 Intermodal

There is bus service to Gillam, 265 km to the south of Churchill. The illustrative table for 2000 D shows a bus-train service that would provide transportation to Churchill at a total cost of $179. A mixed passenger and freight train with basic coach and baggage service was assumed to be used.[14] This would lack the comforts of the present sleeper service with meal and beverage amenities, but the distance and time involved would be much less. Analogous to the situation for the air mode earlier, a transition subsidy is illustrated — in this case $40.

5. Unpublished data provided in personal communication by Statistics Canada, together with data from Société des Traversiers du Québec, *Annual Reports*, 1980–1988.

6. National Energy Board, *Canadian Energy Supply and Demand 1990–2010*, Catalogue No. NE 23-15/1991 (Ottawa: Supply and Services Canada, June 1991). Table 4-12 shows total car stock and truck stock fuel efficiencies improving between 1989 and 2000 by 1.5 percent per annum and 1.4 percent per annum respectively; 1.4 percent per annum for 9 years 1991–2000 would be an improvement of about 13 percent.

7. CCME, *Management Plan for Nitrogen Oxides and Volatile Organic Compounds, Phase I*, CCME, Nov. 1990. The National Energy Board in *Canadian Energy Supply and Demand, 1990–2010*, Tables 11-2 and 11-3, expects $NO_x$ emissions between 1990 and 2000 to fall by about 50% in cars, 38% among gasoline-fuelled light trucks and 20% among diesel-fuelled light trucks, and VOCs emissions over the same period to fall by 40% to 45% among cars and gasoline-fuelled light trucks, and 30% among diesel-fuelled light trucks.

8. State-of-the-art new aircraft are also expensive; however, this does not have as large a bearing on total cost as does the operating cost side. The financial costs — depreciation and cost of capital — associated with even a relatively young fleet would rarely exceed 10 percent of an airline's total costs.

9. *Air Transport World*, several issues — 1989 to 1991.

10. Growth of 30 percent is assumed for 1991 to 2000.

11. See: "ATC turns a profit" and "New ATC Network Comes in on Target," *Jane's Airport Review*, March 1992, p. 10 and pp. 26–29.

12. The smaller airports are those designated as level 4 and 5 in the airport cost analysis: see "Notes to Chapter 3" in this volume.

13. The Manitoba and Saskatchewan early-1991 provincial fuel taxes of 13.6 cents and 15 cents per litre of fuel used for rail travel within these provinces were used. This substantially exceeds their 9 cent and 10 cent per litre taxes on automobile gasoline. (It is noted that Manitoba raised its tax on gasoline to 10.5 cents per litre in May 1991.)

14. Neglecting the Crown corporation status of the logical operator — CN Rail — some financial support or alternative persuasion might be necessary if the carrier were to be convinced to initiate such a service (where potential profits are small and financial risk substantial).

# PREFACE

Volumes 3 and 4 present a selection of research studies prepared for the Royal Commission by its Research Division staff and by various authors under contract. Volume 3 includes: historical overviews and general surveys related to transportation objectives; studies on subsidies, pricing and competition; and a discussion of institutional issues. Volume 4 includes: applied analyses related to determining the cost of transportation; industry studies of the air, bus and rail modes; and studies on travel demand, taxation and technology.

The historical overviews comprise two studies. The first, by D.R. Owram, entitled "Icons and Albatrosses: Passenger Transportation as Policy and Symbol in Canada," examines the evolution of transportation in Canada, with particular emphasis on rail and roads. The second, by George W. Wilson, entitled "U.S. Intercity Passenger Transportation Policy, 1930–1991: An Interpretive Essay," provides a survey and a critique of U.S. transportation policy over the last 60 years.

Two of the general surveys, namely, that by Robin Boadway, entitled "The Role of Equity Considerations in the Provision and Pricing of Passenger Transportation Services," and that by David W. Slater, entitled "Transportation and Economic Development: A Survey of the Literature," discuss issues related to the inclusion of equity or economic development as objectives for a passenger transportation system.

The studies that discuss subsidies, pricing and competition issues include those by Trevor D. Heaver, entitled "Subsidies in Canadian Passenger Transportation"; David Gillen and Tae Hoon Oum, entitled "Transportation Infrastructure Policy: Pricing, Investment and Cost Recovery"; John Blakney, entitled "Competition Policy and Canadian Passenger Transportation"; and Keith Acheson and Don McFetridge, entitled "Controlling Market Power in Weakly Contestable Canadian Airline Markets." Federal-provincial institutional issues are discussed in two papers by Patrick J. Monahan, entitled "Constitutional Jurisdiction Over Transportation: Recent Developments and Proposals for Change" and "Transportation Obligations and the Canadian Constitution."

The applied analyses in Volume 4 include three studies on the cost of transportation. These are "Transportation Infrastructure Costs in Canada" by Ashish Lall; "Road Costs" by Fred P. Nix, Michel Boucher and Bruce Hutchinson; and "Environmental Damage from Transportation" by VHB Research & Consulting Inc. Of the industry studies, that by Steven A. Morrison, entitled "Deregulation and Competition in the Canadian Airline Industry," and that by Ron Hirshhorn, entitled "The Effects of U.S. Airline Deregulation: A Review of the Literature," relate to the air mode. The bus mode is addressed in "An Analysis of the Canadian Intercity Scheduled Bus Industry" by Richard Lake, L. Ross Jacobs and S. T. Byerley. The rail mode is addressed in the study by Charles Schwier and Richard Lake, entitled "VIA Rail Services: Economic Analysis," while airports are considered in "Airport Investment and Pricing Policies" by A. Cubukgil, S. Borins and M. Hoen.

Volume 4 concludes with studies on three further topics. Travel demand is addressed in two studies. The paper by Eric J. Miller and Kai-Sheng Fan, entitled "Travel Demand Behaviour: Survey of Intercity Mode-Split Models in Canada and Elsewhere," is a general survey of demand modelling. It is complemented by Richard Laferrière's study, entitled "Price Elasticities of Intercity Passenger Travel Demand," which calculates various elasticities of travel demand from several models on comparable bases. The impact of taxes on the cost competitiveness of Canadian intercity passenger transportation carriers, both intermodally and with U.S. carriers, is addressed in "Differential Taxation of Canadian and U.S. Passenger Transportation" by Ken McKenzie, Jack Mintz and Kim Scharf. Finally, a discussion of general technology issues and of prospective technology relevant to Canadian intercity passenger transportation modes over the next 25 years is provided in "Notes on Intercity Passenger Transportation Technology" by Richard Lake.

The contribution of those who participated in the editing and translation of all of the four volumes of this report was acknowledged at the beginning of Volume 1. In addition, the Royal Commission staff was ably assisted in the editing of Volumes 3 and 4 by PMF Editorial Services Inc.

# ICONS AND ALBATROSSES: PASSENGER TRANSPORTATION AS POLICY AND SYMBOL IN CANADA

D.R. Owram*

February 1992

## 1. INTRODUCTION

This essay looks at the evolution of Canadian passenger transportation with a specific question in mind. Why is it that Canadians take such a proprietary, even affectionate, interest in issues of long-distance transportation, especially when railways are involved? Over the approximately one and a half centuries of Canadian history in which we have had a reasonably systematic system of passenger transportation, there have been massive changes in the technology and economics of transportation and accordingly in the way in which the public travels. Various periods have seen the dominance of differing forms of transportation. In the pre-railway era, water travel was by far the most efficient and comfortable. Beginning in mid-century, railways provided a fast, competitive means of travel by land and soon dominated both passenger transportation and land-based freight. In the 20th century, the arrival of cars made travel more feasible on roads, which until then had been a secondary means of travel. As this new technology was perfected and increasing amounts of money were spent on the road system, the car initially provided competition for and then largely displaced the train as a means of passenger travel. Air travel, which arose most recently, further displaced rail travel, especially on those longer distance runs where cars had not yet captured the market.

---

* Department of History, University of Alberta.

Water, railways, roads and air all form important segments of Canadian passenger transportation. Of them all it is the railway that seems to possess the greatest symbolic significance. It rose in the mid-19th century as the new technology of the industrial revolution and soon towered over other forms of transport. Just over a century later it began to lose its central position, especially in the area of passenger transport. The number of passengers peaked in 1944, and thereafter an erratic but irreversible decline began. By the early 1970s railway travel was becoming increasingly unfamiliar to the average Canadian. Yet, despite all the changes, railways had an enduring, even mythic, hold upon Canadians.

People in many nations show a special affection for and interest in their public transportation systems, particularly railways. Canadians seem more fervent than most. From the time that railroads first appeared in North America until the present generation, books, films, songs and poetry have glorified the railway and its place in Canada's destiny. Indeed, when Gordon Lightfoot recorded "The Railway Trilogy" in 1962, he may have made Canada one of the few countries in the world to have a popular musical hit that glorified railway construction. That this was so is testimony to the way in which railways have become a part of popular culture in this country. A Grade 7 textbook of the 1950s reasonably asked the question, "Have you ever crossed Canada by railway?" Even if you had not, the imagery portrayed in the book would likely have been familiar. There was talk of the "kindly porter," "the snug upper berth," and the scenic ride through the "famous spiral tunnels." The passage concluded with the statement that "the road of steel has tied our provinces together."[1]

To explore why such imagery has been so important to the national culture is a complex undertaking. This study attempts to understand our national concerns about passenger transportation by tying together three aspects of its development. First, we will look at the evolution of transportation systems and their importance in Canadian history. Second, we will pay special attention to government policy toward both transportation generally and passenger transportation specifically. Finally, we will discuss how people perceive the various modes of passenger transportation and their roles in Canadian society. Obviously, the three themes are intimately connected.

A great deal has been written on Canadian transportation. This is hardly surprising, for transportation is technology overcoming the tyranny of geography. This being the case, the very geography of Canada has determined the central role of transportation in the Canadian psyche. Geography, it has been argued, has always been central to the Canadian sense of identity.[2] Canada is the second largest nation in the world, and yet it has a small and scattered population. Thus, both the diversity of Canadian geography and the sheer magnitude of it have been inescapable throughout history. A vast nation with a small population means that transportation networks are going to be expensive relative to likely traffic. Yet the very distance involved in the geography of Canada makes efficient transportation all the more necessary.

This unfavourable distance/population ratio has resulted in three of the constants of Canadian transportation history. First, transportation—especially long-distance transportation—has been a more important issue in Canadian politics and economics than in many other countries. It is usually one of the items near the top of the public agenda.

Second, the distance/population ratio has led to a paradox that has confronted politicians, the public and businesses throughout history. In numerous instances a particular transportation project has been considered essential for the community or region involved. Yet, all too often, the small population and large distance meant that there was little or no likelihood of the finished work generating sufficient revenue to be economically worthwhile to any investor. The only way to bridge the gap was for government or governments to make the investment in the name not of profit, but of social welfare (real or perceived). As long ago as 1917 economist D. A. MacGibbon summed it up when he said, "Transportation policy has not been viewed merely from the standpoint of commercial and economic convenience. In the final outcome these national ideas have dictated the course of development."[3]

Third, as will be discussed later, transportation in Canada has come to be seen more than in most countries as central to the very existence of the nation. Although both Canada and the United States used the railway to tie together east and west, the links in Canada are more crucial and more vulnerable. Canada, with a smaller population, has always felt a strong pull toward the larger economy to the south. Given the sharp geographic division between the regions of Canada as well as the artificial nature of much of the Canada-United States border, an effective east-west transportation system has from colonial times been thought crucial to Canada's continued independence. The alternative and geographically natural series of north-south interconnections seems to point to Canadian fragmentation and continental integration.

Geography, then, has created particular difficulties for the development of an efficient Canadian transportation system. This is well known, but equally important is how that difficulty has affected the public attitude. To put it briefly, subsidy has been a necessary part of Canadian transportation from the time mass transportation began. The Canadian public, therefore, is understandably conditioned to look upon transportation not as a series of profit-loss decisions by entrepreneurs but as a public good. That public good argument, moreover, has so far focussed more on trains than on airplanes or cars. This is likely because railways have been central to Canadian nation-building and because it is railway passenger travel that is currently threatened. This mood could, however, also apply to other means of transportation if they too seem both vital and threatened.

A great deal has been written about transportation in Canada, but relatively little on the history of passenger transportation. There has been no general study on passenger transport. Nor have those studying specific areas given this topic a great deal of attention. Instead, the emphasis has been on the construction of infrastructure or the movement of goods. Passengers do appear in studies, but there is little sustained description or analysis. There are exceptions to this rule. The emphasis on freight occasionally shifts during points of competition or crisis in the passenger area. Also, post-war developments of a large-scale air industry, which is more passenger dependent than railways, has tended to focus more attention on passengers. Still, that industry has had relatively few scholarly histories, and the passenger area, though important, remains thinly covered.

Part of this neglect results from the overwhelming attention paid to freight issues. Carriers were interested in the revenue passengers could generate, but the major decisions on construction, route, canalization or whatever were made with an eye to traffic in general, without any specific emphasis on passengers. For this reason it is difficult historically to distinguish between passenger and non-passenger issues. Very often they are part and parcel of the same concern. Even after works were completed the emphasis was often on freight. Only in the second half of the 20th century has passenger traffic become a significant political issue. In contrast, controversies over freight rates go back much farther and, as the history of the Crow rates indicates, have been politicized for a very long time.[4] Only by the 20th century were there consistently distinct corporate policies toward passenger and freight services.

## 2. THE ERA BEFORE RAILWAYS: TO 1850

Three characteristics mark the pre-industrial era in Canadian transportation. First, features of terrain and climate governed transport, for neither the technology nor the capital existed to significantly alter natural conditions. Second, because of this, transportation by water was much speedier and economical than that by land. By far the greatest movement of passengers and freight was along the natural water routes of North America. Third, toward the end of this first phase, the more advanced technologies of Europe began to have an effect on the transportation infrastructure of British North America. Steam power and the modification of the waterways by dredging and canals both improved the transport system and hinted at the more extensive applications of technology that were to become practical in the near future.

The Europeans who came to settle in North America were challenged by the vast and unknown landscape. Dense forests, ranges of hills and low mountains, seasonal freeze-ups and spring thaws all slowed travel. In the first centuries after their arrival Europeans did not have the population, the capital or, for the most part, the technology to significantly alter that landscape. As with the natives with whom they worked and competed, the Europeans had to operate within the North American environment. Fortunately, as any map of Eastern Canada indicates, the early colonists also found the landscape a useful ally: the strings of lakes and rivers provided an unparalleled access to the interior of the continent. The waterways thus became the highways of the colonial era. For more than two centuries the transport of both people and goods largely followed the rivers.

In contrast, travel on land was difficult and slow. Even at their best, roads in pre-Confederation Canada were inferior to waterways as a means of moving people or goods. Also, practically all the roads of this era were seasonal. Good winter and summer travel was possible, but spring-break-up or the transitional fall frosts and thaws quickly rendered roads impassable. These facts shaped road policy. Because land transportation was so difficult in the forested eastern part of North America, settlement clustered around water and looked to water as a means of transportation. There was, for example, no road outside of Quebec City until the 1670s, more than half a century after settlement. Not until the 18th century was there really a system of roads or a structure of government to develop them.[5] Even then they remained feeder systems for the most part, directing people and goods to the more efficient waterways.

Thus European settlements grew along the waterways, and European travel, as with native travel, followed those watercourses wherever possible. New France, whose settlers explored and developed trade far beyond the confines of the St. Lawrence Valley, has been characterized as a river empire.[6] By the 18th century this empire reached west to the Prairies and south to the mouth of the Mississippi. This land was not transformed or conquered, and certainly no large-scale transport system was imposed upon it. Instead, the French operated through alliances with powerful tribes, and their travel in the region was on a small scale and conformed, as always, to the waterways. The Europeans had no technology suitable for such wilderness travel, and thus they adopted the natives' lightweight birchbark canoe. The great advantage of this was that it could be hauled over the numerous portages without great difficulty.[7]

By the 18th century European transportation technology had been introduced, at least in the more settled regions of the St. Lawrence. Flat-bottomed bateaux and local schooners operated between Quebec City and Montreal. Later, after the British conquest of 1763, the Durham boat (a keeled boat) joined the bateaux and schooners. These technologies extended westward to Lake Ontario by the late 18th century as the Loyalists and other immigrants began to settle the region that, in 1791, became Upper Canada.

Within this framework of small craft and a thinly populated continent, passenger transportation was a non-specialized and largely makeshift activity. A barge owner heading upriver or along Lake Ontario would sell space on his unsheltered barge for either freight or people as demand might have it. A crude tent might be erected, used by both owner and passengers, and food would be supplied as a part of the fare. None of this was fixed, however, and there were no formalized agencies or companies engaged specifically in the movement of passengers until around the turn of the 19th century. Government, for its part, had few regulations and no investment as such in the provision of passenger transport. Moreover, even this rudimentary form of travel was limited in two ways. First, it was seasonal. When the river froze (as it did for four months of the year), those who wished to travel had to use sleighs (where they could get through the woods) or snowshoes. Needless to say, long-distance travel in winter was undertaken only under the most urgent circumstances. Second, even under ideal conditions, water transport was slow, especially against the current.

In the first years of the 19th century, passenger transportation began to change. For one thing, the growing population of Lower Canada and the rapid development of the frontier colony of Upper Canada increased demand for organized travel. Entrepreneurs saw that responding to this demand was potentially profitable. Moreover, the harnessing of steam, which was such an essential part of the industrial revolution then occurring in Great Britain, soon affected North American transportation.

In 1807 Robert Fulton demonstrated the practicality of steam power by successfully taking his ship, the *Clermont,* upriver from New York to Albany. Within two years a British North American launched the *Accommodation.* This initial craft was small and not really able to handle the currents of the St. Lawrence. A more powerful craft followed within a couple of years, however, and by the 1820s steamships were common on the St. Lawrence and Lake Ontario. By the 1830s they could also be seen on lakes Erie and Huron. Though steam engines were not yet perfected, these ships provided a degree of freedom from the current and the weather: they could work against the wind. Also, in terms of travel time, they brought points closer together. It was possible by the 1820s to travel from Montreal to Quebec City in about 24 hours. By 1835 a trip from Kingston to Toronto took about the same time, at least under good conditions.

Steamships not only improved the technology of passenger transport but also were of a scale that encouraged some specialization. These ships were not the small craft of just a few decades before, picking up a few passengers as demand warranted. The largest steamships could transport up to 900 people,[8] and travel on this scale had to be scheduled to let customers know of sailings. By the 1830s formalized passenger transport existed between Quebec City and Niagara, with (more or less) regular schedules, fixed fares, sometimes different classes of accommodation and (more or less) comfort.

As both trade and passenger transport became formalized and larger scale, government became increasingly involved, passing various regulations to ensure the safety of steamship passengers. Moreover, contracts to carry the Royal Mail could provide extremely important subsidies to steamship owners seeking to establish a profitable system along the St. Lawrence-Great Lakes system. The government also became involved in another way, one that established a precedent for future activities. Before long, those operating the ships and those travelling or trading along the St. Lawrence began to look to government for help in developing the infrastructure of the transportation system.

The St. Lawrence system was a superb natural highway into the interior of the continent, compared with any available elsewhere along the eastern seaboard. It was far from uninterrupted, however. Montreal and Lake Ontario were separated by a series of rapids. From the time that Jacques Cartier had been prevented from continuing his quest for China by the first of these (hence La Chine or Lachine rapids), travellers had had to make a series of time-consuming portages. Farther inland, at the escarpment separating lakes Ontario and Erie, was the spectacular break of the Niagara Rapids and Falls. Rapids on the alternative route into the interior, the Ottawa River, made travel difficult in that direction.

These rapids were an inconvenience, but for the light canoes and small-scale trade and transport common before the late 18th century they were tolerable. Portaging was simply part of the cost of travelling and trading in the interior. By the 19th century, however, the introduction of larger craft made the obstacles more costly. Moreover, the interior was no longer merely a sparsely populated hinterland. Upper Canada was growing quickly. From a practically unpopulated region in 1780 it grew within two generations to be the largest of the British colonies in North America. Already, by the end of the war of 1812, there were approximately 100,000 people there, and by 1830 that figure would more than double. Demand for cheap and efficient passenger and freight traffic was growing apace.

The result was a clamour for canal construction. The detailed history of this first great transportation enterprise has been told elsewhere, and only the most basic details need to be repeated here.[9] The effort began shortly after the war of 1812, with two separate ventures. One was in Lower Canada, where a group of businessmen decided to construct a barge canal around Lachine Rapids. The other was in Upper Canada, where local businessman William Hamilton Merritt planned the Welland Canal between lakes Ontario and Erie. Both were constructed, though neither their quality nor size was very satisfactory in the early years. Then, in the 1820s the British government provided assistance to the Canadas by constructing the Rideau Canal, linking the Ottawa River to Lake Ontario. By the 1830s it was thus possible, with the right type of vessel, to travel without portaging from Montreal to Lake Erie. The canals were often shallow, with as little as a five-foot (1.5 m) draft, and the route via the Rideau Canal was circuitous.[10] In fact, for practically all freight and for most passengers, transshipment was still the norm. The small craft suitable for the canals were not suitable for the open waters of Lake Ontario.

In 1840 the two Canadas were united, and with improved fiscal capacity as well as a loan guarantee from Great Britain, they made a major effort to canalize the remaining rapids between Montreal and Lake Ontario and to deepen and improve the Welland and Lachine canals. By 1848 there was uninterrupted navigation to a depth of nine feet (2.7 m) from the ocean to Windsor. This, in combination with the refinement of steam-powered vessels that had taken place by the 19th century, revolutionized passenger travel. The passenger who could afford the fare was now able to travel in comfort by water to all of the major centres of Canada West (as Upper Canada had become in 1840). Moreover, the time of travel had been cut, though more important was the relative cheapness of moving heavy freight.

The canal era was a significant one in colonial Canadian history and was one of the key events marking the transition from a pioneer to a settled economy in central Canada. What is especially important for this study, however, is that the construction revealed two important and related paradoxes. First, the cost of canal construction demonstrated the already mentioned paradox brought on by Canadian geography. As a land of vast distances, Canada very much required an efficient transportation system. Yet the very distances involved and the small population made it extremely difficult for businessmen to undertake such works successfully. Though investors, businessmen and government officials might believe that transportation works were crucial, the necessary funds were still difficult to come by.

Local capital was scarce, and international capital was hard to attract for the very sensible reason that many of the works, however necessary, were unlikely to pay the cost of construction.[11]

This was the case with the Welland and Lachine canals. The Welland Canal Company and the Lachine Canal Company, both chartered as private companies, quickly found that they could not raise sufficient funds to do the job. As early as 1819 the Lachine Canal, which had already been subsidized by both the colonial and the imperial government, was taken over by the government of Lower Canada. In Upper Canada the Welland Canal went through a more tortured process of acquisition, but the final result was the same. As early as 1824, wrote the historian of that canal, the "Welland Canal Company was already degenerating into a privately controlled institution for the disbursement of public funds."[12] The disbursements continued, but in a precedent that would echo through other financial crises the government also began to assume more and more control. By the later 1830s it was the largest shareholder, and by 1841 it had assumed direct control of the work.

By the time of the union of the Canadas in 1841, the government owned and operated the canal system. It was built, but not because it was seen as a paying proposition. Indeed, the construction and operation of the canals were always money-losing propositions for the government. Rather, the system was built because the benefits to the population were thought to make the works necessary. This raises the second paradox. The governments were only a little more able to afford the transportation systems than private enterprise. The canal systems imposed a severe fiscal strain on the Province of Canada. Before the union the Welland Canal had nearly bankrupted Upper Canada. The fiscal strain imposed by expensive transportation projects was not confined to the colonial era. As discussed below, it continued well into the 20th century, and echoes of it linger still.

There are many reasons why government allowed itself to become so deeply entangled financially. First, as various studies have shown, the dominant political groupings of the colonies were commercially oriented. They all saw growth as the key to the colonies' future and often, not incidentally, to their own.[13] Second, given this assumption, government was trapped by the same paradox that affected society as a whole. If the work was essential, how could it be abandoned? Third, this problem had an extra dimension at the government level. The canal system had always been promoted as an endeavour that was both progressive and patriotic. This was the way in which Canada could compete with the United States for the traffic of the mid-west. To fail to complete the system could jeopardize not only the national prosperity but also the national existence.[14] It was an argument that was to appear many times in the future.

The burden of canals had nearly bankrupted the governments of colonial British North America. Then, just as the canals were finished and as the government undertook the ongoing cost of operating and improving them, a new and vastly more expensive transportation technology made its appearance.

## 3. LAND TRAVEL DURING THE GREAT RAILWAY ERA: 1849–1920

There was no parallel on land to the significant improvements wrought before 1850 along the waterways of British North America. Yet land travel was a necessity. Settlers needed access to their farms and had to carry their goods to market. For those on the fringes of civilization, access to decent roads was critical, from both an economic and a social viewpoint. Bad roads were ongoing matters of complaint in the pre-Confederation period. As early as 1799, grievances in Upper Canada were focussed on the state of roads. As one official document concluded, "The present wretched state of the means of communication between the several parts of the Province" almost paralyzed commercial and government activities much of the year. The government, it was urged, should take immediate steps "to remedy so serious an evil."[15] The evil was not so readily overcome however. In 1819 a campaign of complaint against government focussed on the inadequacy of land communication.[16] The 1837 rebellions in Upper Canada were in many ways a back-settlement rebellion against the dominating forces on the lake-front, including rebellion against the indifference of the colonial elites toward the road system.

By the 1840s the mood of rebellion had faded, but the farmers' sense of grievance remained. The elaborate canal plans of that decade brought a protest from those who warned that only a few miles inland farmers "lived in a country without practicable roads at a distance from society and civilization." There, because of the lack of effort and direction by government, "they found themselves shut up in the gloomy prison of the eternal forest, excluded from the means of education for their families, from the consolation of public worship, from the blessings of civilized society. But they could not escape."[17] Such imagery rang most true to those inland settlers who, in the 1840s, were pushing north toward Lake Simcoe or westward from London. Even for those in more settled areas, in Nova Scotia and Canada East as well as on the frontier of Canada West, the rhetoric was far from foreign. There were exceptions, but roads in British North America generally remained primitive even a decade or so before Confederation.

Aside from the obvious fact that roads were not very good, however, it is difficult to discern any clear stages in road policy or development before 1850. For one thing, the records of the pre-Confederation road system are sparse and imprecise. This is partly because the road is a much more amorphous concept than, say, is a railway. A railroad either exists or it does not. The same cannot be said for roads. In the years before the car, the trail, suitable only for people on foot and perhaps in existence long before European settlement, became a more defined route passable at least part of the year by horseback. Portions of the route then might be widened and improved to allow carts and wagons and ultimately be surfaced with one of the available technologies of the era. Bridges would replace fords. In all of these considerable changes, however, it is impossible to say for sure whether a new road was created. Yet this is exactly the progression followed by many of the land-transportation routes in the pre-Confederation era. The story of land travel from early New France through to the eve of the railway is one of gradual improvement rather than of any great technological breakthrough such as occurred with the railway or of any vast government effort as was the case with the canal system. Roads evolved as the poor cousins in the transportation system as needs demanded and resources allowed.

Both the limitations of government and the marginal position of roads dictated how road construction and finance were handled in the colonial era. Roads were treated as a local matter. At the extreme this placed the responsibility for the maintenance of a road on the family whose property it fronted. Generally, however, local governments were responsible for roads. Those local governments could and occasionally did use taxation to support the road system, but the general practice was to employ statutory labour. First in New France and then in colonial British North America, legislation required citizens to work for so many days a year on the roads of their locality. Those who did not have the inclination to do so could commute their statutory labour by means of a payment to the local government.

Contemporary and historical sources unanimously agree that the statutory system presented serious problems. First, the level of maintenance and construction on roads depended on the enthusiasm, skill and willingness of the individual settler or, when organized into crews, the competence of the pathmaster and his amateur crew. Second, the effort made depended on the ability of local officials to bring out the population to undertake the work. It was also difficult to ensure that absentee landlords did anything at all along their property frontage. Thus, the quality of an individual road varied considerably from property to property, much less from county to county.[18]

There were always exceptions to the rule that roads were considered local matters. As far back as the 1720s the government of New France had designated certain key routes "chemins royaux" and had used colonial funds to construct and improve them. They had ditches and were 24 feet (7.3m) wide, compared with the 18-foot (5.5m) local, usually undrained, road. Likewise, in the British colonies, the colonial governments got involved in developing what were considered the most important roads. Governor Simcoe of Upper Canada used military funds for work on Yonge Street and the Dundas Road. In Nova Scotia the early 19th century government provided assistance for the main road system, which ran outward from Halifax to settlements like Antigonish, Yarmouth and Shelburne.[19] There were also the "turnpike trusts." These were roads built and maintained by private corporations in return for the tolls received. The main government roads and the toll roads were more likely to be maintained sufficiently to allow wagon as well as horseback traffic, to have bridges over at least the deeper streams, and to be drained in such a way that they could be kept open for a greater period of the year. They were still seasonal and relatively primitive even decades after settlement began in the region.

By the 1830s or 1840s the passenger setting out on a journey between two relatively major centres could hope to travel a road passable for horse and, optimistically, for wagon. The road itself would have been cleared of trees and brush to a width of 16 to 24 feet (4.9 to 7.3m), though shortage of funds or indifferent statutory labour meant the brush continually encroached upon the road and, along with fallen trees and branches, provided recurring obstructions. With very few exceptions, the surface of the road was earth and, of course, highly susceptible to weather conditions. Heavy rain, spring breakup and similar events could quickly render even the best roads in British North America impassable.

Even when the ground was passable, the traveller faced problems. First, there were many low-lying, swampy areas that even a minor rain would turn into a quagmire. In these areas the technology most favoured by road builders was the so-called corduroy road. This consisted of logs (sometimes halved but usually not) laid across the road. Corduroy roads provided support for horse and wagon and prevented vehicles from becoming stuck. The rough surface also slowed traffic and was notoriously uncomfortable. Corduroy roads were necessary and common. They solved the problem of mud but only reinforced the image of land travel as slow and uncomfortable.

Superior technologies were also available. The plank road, which had sawn planks rather than logs, provided a smooth, fast ride by wagon. It was used in parts of the lumber-rich areas of New Brunswick and the Canadas. Even at its peak in the 1840s, it constituted a small percentage of road mileage, however, and required continual maintenance. Unless properly repaired, a plank road would within a few years become impassable because of the rotting and breaking of the surface.

Best of all the technologies was macadamization. The macadamized road consisted of a base of large rocks, progressively smaller rocks above and then gravel on top. In use in Great Britain by 1815, the technology crossed the Atlantic to British North America by the 1830s. It became increasingly common through the next couple of decades, especially with toll-road companies that sought to advertise their superior product. The reality was somewhat different from the rhetoric. True macadamizing was very rare in pre-Confederation British North America. With the exception of a few turnpike trusts near Montreal, the great majority of macadamized roads were really only gravelled. The firm base was never installed because it was too expensive. As a result, the so-called macadamized roads in Canada had neither the durability nor smoothness of the properly macadamized road.[20] Even primitive Canadian macadamization was a luxury, however, reserved for the major roads near urban centres or along certain turnpike trusts. The travellers of the 1850s, for example, might journey out of town on a gravel surface, but within a few miles they were likely to find only bare earth, with corduroy used in low-lying sections.

Rivers and streams also provided serious obstacles. Bridges were expensive to build, and colonial authorities avoided construction if at all possible. Travellers usually had to ford streams. Larger bodies of water also prevented easy travel. Often roads went miles off line to a suitable ford. Where bridges had been built, spring floods or severe storms often washed them away. Not until local and provincial public works became more organized around mid-century was substantial improvement made in this area.

The long-distance traveller on even the best roads could not expect an uninterrupted, dry, passable road surface over a long journey. If at all possible, travellers sought alternative ways to reach their destination. The lack of road traffic only discouraged further investment or effort. The roads simply could not compete. Typical was the York (Toronto) to Kingston Road shown in Figure 1. Pushed through in the years after 1815, the road was the major connection for the two largest settlements in the colony. Yet it was impassable for several months each year, required numerous fords, and was always threatened by the encroaching forest. Even at the time of the union it was in part a mere horse trail through the forest, poorly maintained and of marginal importance to all but local travellers.

Despite the obstacles, formalized systems of passenger transportation did develop. By the mid-18th century, stagecoach lines had been established in New France. There was also stagecoach service from Halifax to Windsor in Nova Scotia in the 18th century.[21] By the early 19th century there were regular coach services in the two Canadas and Nova Scotia and New Brunswick. Companies were chartered by the relevant legislature and in return for guarantees of service were often given the contract to move the mail. By the 1830s there was a well-developed stagecoach system running between established settlements. The Montreal–Quebec City run, for example, took place two to three days a week and could be done — under ideal conditions—in two days. But then each day involved 16 hours of bone-jarring travel![22] Less frequent were feeder services running from small inland pioneer settlements to urban centres.

An early 19th century guidebook was pitiless in its denunciation of the stagecoach system, arguing that the roads are "poor" and "the surface rough, the bridges wretched, and the attendance at the inns defective. . . ."[23] For a stage to average five miles per hour (8 km/h) over any distance was to do well. It is hardly surprising that the stagecoach system had little enthusiastic

support. It did have advantages at certain times of year, but it was seasonally restricted by the condition of the roads. Once away from the lake or river, therefore, Canada's transportation system was slow, uncomfortable and dependent upon the weather.

In all these ways, improvement over the last 200 [illegible] had been marginal. It is against this background that the tremendous revolution brought by the railway has to be viewed.

The first locomotive with sufficient power to justify commercial use was George Stephenson's British locomotive, the *Rocket*, which covered 70 miles at an average speed of 15 miles per hour (24 km/h) in 1829. Unremarkable though such speeds might be even a few years later, they were revolutionary at the time. This 70-mile trip was accomplished at the highest rate of sustained speed that man had ever experienced, and almost immediately railway lines were appearing in Great Britain and elsewhere. It was perhaps this sensation of speed and power that so quickly captured the public imagination. Images of power and speed were especially appropriate to the mood of the Victorian era. As many studies have shown, the possibilities raised by the industrial revolution, the effective enfranchisement of the middle class by the Reform Bill of 1832, and other measures convinced societies of the Western world that progress was the natural destiny of humanity. For the British subject, unsurprisingly, the centre of that world's progress was at home.[24] The proof of the progress was, for all its problems, the industrial revolution. Technology, combined with the entrepreneurial instinct, had brought material improvement, moral uplift and the spread of political liberty. And there was no more potent symbol of the power and might of industrialism than the railway. The steam locomotive became a symbol for the accomplishments of the age.

Canadians fully accepted the symbolism of the railway and, of course, feared what would happen if they were left behind. Thus, despite the horrendous costs involved and the small population of the colonies, various enthusiastic newspaper articles appeared from the 1830s onward extolling the wonders of the railway and asserting the need for immediate construction. It was in 1849, however, that the classic Victorian image of the railway was published. In that year well-known Canadian engineer Thomas Keefer published a tract with the pretentious yet appropriate title, *The Philosophy of Railroads*. The pamphlet was widely distributed, going through three editions in English and one more in French within four years.

For Keefer, the steel and steam technology of railways was an almost mystical means to free Canadians from the tyranny of nature. It is no accident that he begins his tract with a reference to the seasons: "Old Winter is once more upon us, and our inland seas are 'dreary and inhospitable wastes' to the merchant and to the traveller. . . ." The energetic activities of the colonizer and trader had been shut down. "The animation of business is suspended, the life blood of commerce is curdled and stagnant in the St. Lawrence." It did not have to be that way, for the Americans, always a powerful point of comparison, remained unaffected by winter. "Far away to the South is heard the daily scream of the steam-whistle — but from Canada there is no escape: blockaded and imprisoned by Ice and Apathy."[25]

This contrast between progress and backwardness, between action and imprisonment, continues throughout Keefer's pamphlet. For though there are facts and figures, pragmatic arguments and suggestions, the tract is above all a morality tale. Indeed, Keefer's work is quintessentially Victorian in its linking of material and moral progress. In the centre is the hypothetical village of "Sleepy Hollow." With the arrival of the railway a spirit is engendered in the village that "is not confined to dress or equipage, but is rapidly extended to agriculture, roads, and instructive societies, and finally exerts its most powerful influence where it is most needed — in the improved character it gives to the exercise of the franchise." For where the railway went, enlightenment followed. "Poverty, indifference, the bigotry or jealousy of religious denominations, local dissensions or political demagogueism may stifle or neutralize the influence of the best intended efforts of an educational system; but that invisible power which has waged successful war with the material elements, will assuredly overcome the prejudices of mental weakness or the designs of mental tyrants" [26] The railway had gone from being an instrument of transport to a general agent for material improvement to, ultimately, the major civilizing force of the modern age.

Keefer's rhetoric may have been more inspired than most, but it both fit the age and reflected the dozens and then hundreds of pamphlets, monographs and newspaper articles that came out in the first phase of railway development in Canada.[27] Moreover, for all the hyperbole and propaganda, it is true that railways had a tremendous impact on the life of the average person. They transformed metropolitan-hinterland relationships, made inland transport cheap and rapid, freed travellers for the first time from the tyranny of weather, and quickly became the largest industrial concern in British North

America.[28] All of this reinforced the Victorian predilection to see railways as a metaphor for the progress of their society. Sudden bankruptcies, crooked schemes and the tremendous influence of railway barons on politics did not seriously affect this belief. For whatever the faults of the individual, the railway represented progress, and, it must also be remembered, the Victorian's notion of progress was a seamless web in which material and moral improvement were seen to be linked.

Keefer's pamphlet came at an appropriate time. The year it was published saw the beginning of the first serious railway construction in Canada. In 1849 there was only 66 miles (106 km) of railway in all of British North America. Eight years later there would be 1,800 miles (2,900 km). Millions of dollars (mostly British funds) would be invested (the Grand Trunk line alone cost $67 million), and by the time it was all over many lines found themselves overextended and in debt. Receiverships followed close upon completion of construction.[29]

As with canals, details of the first phase of railway construction and finance are well described in many works and need not be recounted here.[30] Basically, two types of railway were developed in this first period. One type was a feeder line, either to American lines or, more commonly, to water. Nova Scotia linked inland communities and the three coastlines by rail. In Canada West, railways like the Canadian Northern tapped the growing hinterland from Toronto to Aurora, Newmarket and ultimately Collingwood. The other type of railway was more ambitious. It was a trunk line designed not to feed the lakes but to provide a land-transportation axis from east to west. Both the Great Western and, most important of all, the Grand Trunk were this type. The latter, running from Sarnia to Montreal and then Quebec City, became the industrial giant of the age and a major force in the commerce and politics of Canada until World War I. By 1860 British North America had some 2,000 miles (3,000 km) of railways, most, as Figure 2 indicates, located in Canada West.

The relevant governments played a vital role in the evolution of these railways — in the negative decisions it made as well as the positive. Moreover, the decisions made during this first construction boom created precedents for government policy that lasted much longer than many of the railways then built. First, the Government of Canada determined that railways should *not* be directly built and operated by it. Likewise, the Government did not assume responsibility for such support systems as railway stations like it did for harbours or, much later, airports. In all of this, the lessons of the canal era were crucial. Canals had led to tremendous financial strain, and their costs were nothing compared with the huge outlays needed for railways. At the same time, the Government was under the same pressure to develop railways as it had been earlier to develop canals. The railway, as Keefer's pamphlet argued, was crucial to the whole destiny of this young colony. Thus the Government sought to steer between the two extremes.

Its strategy was to use indirect and occasionally direct subsidies. The single most important means was provided by the *Railway Loan Guarantee Act* of 1849. As the title implies, this Act allowed the railways to obtain guarantees on bond issues from the Government under certain conditions.[31] Such a guarantee removed much of the risk to the investor and made it feasible for entrepreneurs to tap the large capital markets of Great Britain. The *Municipal Loan Act* of 1852 allowed cities and towns to draw upon provincial credit guarantees if they wished to support railway projects in their area.[32]

In theory these acts provided a means of support for railway construction, at least under ideal conditions, without actually costing the taxpayers a penny. Not surprisingly, it wasn't that tidy. Railways borrowed heavily, and municipalities proved especially prone to railway fever. They had to, for the place of their community in the future hierarchy of trade and power depended on the railway. Many railways came crashing down, required reorganization or defaulted on their bonds. The Government had to step in on several occasions to rescue the railway or the overloaded municipality. By 1857 the first phase of railway construction was over, and for the next decade governments, companies and British bondholders sought to recover from the spree. All of this was reasonably predictable. Hundreds of millions of dollars had been spent in a region with a very small population and capital market. Still, the railways were in place, and this revolutionized Canadian transportation.

The railway affected the structure of industry in the colonies and the metropolitan-hinterland relationships, while the actual construction provided a major impetus to capital formation in the colonies. Those cities, like Toronto, that were the terminal points of major railways were the greatest benefactors. Extended hinterlands, new industries and the presence of considerable financial empires distinguished these cities from smaller pretenders and did much to establish the pattern of urban relationships that are still familiar today. For people as well as commerce the railways revolutionized life. For the first time it was possible to move as comfortably and rapidly on land as it had been on water. The farmer or merchant living inland in Galt or Barrie or elsewhere now had easy access to local towns or the larger cities. The hold of the seasons upon travel was considerably weakened and, with the improvement of snowploughs over the next decade or so, effectively broken. Year-round travel was now possible for the first time. In that sense Thomas Keefer's opening sentences about the hold of winter were entirely appropriate.

## THE PROJECTS OF CONFEDERATION: THE RISE OF THE RAILWAY AS NATIONAL SYMBOL

Both railways and canals had been seen by governments in the colonial era as developmental necessities worthy of support. The projects had often had pro-British (that is, anti-American) overtones as well. It was at the time of Confederation, however, that transportation issues became linked closely to nationalism. Confederation was accomplished in a mid-Victorian era, when faith in the industrial revolution and technological progress was high. One of the major impetuses behind Confederation was also physical expansion by the Province of Canada, which wished to "extend eastward to a port not in American hands and westward to new areas of trade and settlement."[33] The new Dominion was thus soon faced by the problem of continent-wide distances that only the railway seemed able to resolve.

The Province of Canada was not alone in seeking railway arrangements as a part of Confederation. In the Maritimes, early railway projects had brought the colonies near bankruptcy. The failure in the early 1860s of a projected railway link between Halifax and Quebec City had also left a feeling of bitterness, for the "Upper Canadians" were widely blamed for its collapse.[34] Those who supported expansion into the vast Prairie region realized that only the railway would make meaningful connection to the rest of Canada possible. Still farther west, British Columbia's entry into Confederation in 1871 made sense only if there was to be a transcontinental railway. Great Britain, having experienced the difficulties of moving troops overland during an Anglo-American war scare in 1861, was also supportive, especially of the Intercolonial Railway project.[35] Railways thus became linked with the very process of nation building. The Intercolonial Railway was actually written into the Constitution, the *British North America Act, 1867* (s. 145), making Canada perhaps the only nation in the world with a railway as part of its fundamental law. Once the precedent was established it was tempting to continue to invoke it. British Columbia's entry into Confederation was rewarded with a promise of a rail link to the Pacific; Prince Edward Island's, with a federal takeover of the bankrupt Prince Edward Island Railway.[36]

The close connection between the political act of Confederation and the economic policy of railway development had important consequences. First, the imperative of national development led the Government to make exceptions to its policy of avoiding direct construction and ownership of the railway. The Intercolonial had to be built, but as one of Canada's senior engineers warned, "it offers no material for a flattering prospectus; we could not invite it to the attention of European capitalists as presenting an eligible investment for their surplus funds. But for the establishing of those intimate social and commercial relations indispensable to political unity . . . the railway is a necessity."[37] There was thus no choice for the Government but to build it itself.

Dependence on the Government brought problems. For example, the choice of route — the so-called northern route — saw purely commercial considerations downplayed in favour of military and political ones. Also, there were fears of patronage (for good reason, given the times), and a cumbersome, three-layered authority was set up: the chief engineer of the Department of Public Works, the Government and appointed commissioners. Finally, once the taxpayer's money was involved, decisions on quality of construction became political topics and led to a great deal of wrangling back and forth.[38] Not all the problems were resolved satisfactorily, but by 1876 the first through train ran from Halifax to Quebec City.

The second implication of this national project was that having been built it could not easily be abandoned when it proved costly to operate. The Government had hoped to get rid of it by sale or lease to a private operator such as the Grand Trunk. The Intercolonial was no more attractive to operate than to build, however, and it became a Government railway line, operating at a loss from the day it was opened. Before long the Government also acquired another railway, along with a province. Prince Edward Island had resisted Confederation but had not been able to resist railway fever. By the early 1870s the Prince Edward Island Railway had brought the small colony to the edge of bankruptcy, and Canada moved quickly to offer to bail them out: it would assume the inefficient and badly built railway in return for that colony's entry into the Dominion. By 1873 the deal was completed, and the Department of Public Works found itself in charge of yet another railway. It too operated at a loss.

The Government's involvements in these Maritimes railways were patently political bargains. Many people in the Maritimes since then, therefore, have seen adequate service for passengers and reasonable freight rates as not just another regulatory decision but a part of the basic constitutional package of Confederation. In the 1920s the powerful Maritimes Rights Movement sprang up to protest apparent federal indifference to a region undergoing economic decline. Much of the rhetoric and anger of this movement, as we will see, were focussed on Government management of the Intercolonial.[39] Likewise, during the more recent controversies over VIA Rail service, Maritimers pointedly argued that the Intercolonial was a part of the Confederation pact.[40]

The scope and cost of the Maritime railways were nothing compared with the greatest railway project to come out of Confederation: the transcontinental Canadian Pacific Railway (CPR). The story of the construction of the CPR has been told on numerous occasions. Suffice it to say here that after some failed organizational attempts in the early 1870s, there was desultory and half-hearted construction, accompanied by energetic surveying in western Canada in the late 1870s. Then in 1881 the Government enticed the famous "Syndicate," headed by James Hill, George Stephen and Donald Smith, to undertake the work in return for suitable incentives. Remarkably, that work was completed by November 1885. Unlike the eastern railways discussed above, the Canadian Pacific soon became profitable and astounded its creditors by quickly repaying outstanding loans. It rapidly became the most important corporation in Canada and one of the major railways of the world.

Government policy toward the CPR was based on traditional forms; that is, the Government avoided ownership and gave subsidies instead. Some direct Government construction was undertaken in the 1870s by the Liberal administration of Alexander Mackenzie, but the major portion of the line was constructed on principles derived from earlier railway ventures in Canada and from the United States. Specifically, the Government offered the investors three types of subsidy. The first, borrowed from the Americans, was a land grant — the famous 25 million acres. The second was cash, initially $25 million. The third was a series of privileges accorded the CPR: the remission of duty for construction materials, the promise of monopoly between the main line and the border for 20 years, and other lesser provisions. As construction went on and the company ran into financial difficulty, additional support was given.

There has been much debate over the years, and especially recently, about whether all of these subsidies were needed.[41] It is unlikely the question can ever be answered conclusively, but from the point of view of this study that is less relevant than the simple fact of subsidy. For the subsidies created an ambivalence in the relationship of the CPR with the Government that persisted thereafter. On the one hand, the CPR is not a purely private work. The CPR is often seen by the Government and the public as having a particular public service role, resulting from the support it was given at the beginning. On the other hand, as the CPR has pointed out at various times, it is a private company. Once it completed construction, it repaid Government loans and operated on a self-sufficient basis thereafter. As a CPR publication of the 1940s put it, these government supports should be seen as "payments for service rendered" rather than as subsidies at all.[42] From this perspective the CPR has a primary duty to its shareholders to uphold its profitability and therefore to operate freight or passenger services as commercial needs dictate and not as an agent of social or political policy.

The most important aspect of the CPR, however, is the standing it has assumed in the Canadian psyche. No other railway, and perhaps no other commercial project in Canadian history, has assumed such an important place in the public consciousness. The CPR has become a legend and a symbol in both scholarly and popular history, and the nature of that legend says much about the values Canadians attach to their railway system.

The CPR was controversial from the very beginning. The early attempts to create a viable private company collapsed amidst the Pacific scandal of 1873. Along the way it brought down the government of John A. Macdonald. Then, when the Syndicate was formed in 1881, there was a great deal of controversy over both the principle of vesting such massive power in one group and some aspects of the subsidies, especially the notorious monopoly clause.[43] From potential investors came the warning that the railway could look forward to a "long and dreary season of unprofitableness."[44] The controversy only intensified when the railway was completed. Almost immediately Manitoba attempted to subvert the monopoly clause of the charter, and farmers' groups were protesting the high-handed attitudes of the railway before the 1880s were out. Resentment against the power and policy of the CPR flared regularly across the West. Freight rates, grain-elevator policy and the need for branch lines made the CPR a much-loved object of hate through Western Canada. Indeed, many of the agrarian organizations and reforms that came about over the years owed much to a common hatred of the CPR.

Even more powerful than this distrust of the corporation was a national enthusiasm for the railway itself. Titles like *The Romance of the Canadian Pacific Railway, Steel of Empire, Canada's Great Highway* and, best known of them all, *The National Dream* reflect something of the romance and glory attached to the railway over the years. Even in the West the predominant writing on the railway has tended to distinguish between the corporate rulers, eastern and callous, and the railway itself — a vital lifeline on which westerners worked, travelled and depended for trade.

Part of the image of the railway has much to do with the sheer ambition of the project. As the advertising copy for the 1949 movie "Canadian Pacific" dramatized it, this was "The story of a railway that couldn't be built . . . but was."[45] This romantic image of the CPR began with contemporary accounts of the adventure and hardships involved in its construction. The treks through uncharted wilderness, the bogs of northern Ontario, the hardship and even the deaths all became a part of the glamour of the project itself. Equally, early travellers over the line — often before the line itself was complete — related details of the hard work, the danger and the adventure that surrounded the project.[46] The CPR, still desperate for money and respectability, did everything it could to encourage such writing. The travel of the prestigious British Association for the Advancement of Science over the line in 1885, for example, led to good publicity.[47] So too did the transportation of troops west to suppress the Riel rebellion in the spring of that year.

As time went on, the romance of construction was reinforced by a sense of nostalgia and the important fact that the dubious venture of the railway had in fact succeeded. As the Canadian Pacific survived and then prospered, repaid loans and made profits, the earlier uncertainty disappeared. The very decision to act became as romantic as the action itself. "It was in itself an act of splendid audacity for a people of less than four millions in number to start on the task of throwing a railway across an immense and almost uninhabited continent to the shores of the Western sea," wrote one enthusiast in the 1920s.[48] The actual construction, for its part, became a part of the great Canadian epic of taming the wilderness. When engineer Sandford Fleming witnessed the laying of the last spike he linked it to the earlier generations of fur traders, "the Mackenzies, Frasers, Finlaysons, Thompsons, M'Leods, MacGillivrays, Stuarts, MacTavishes, and M'Loughlins, who in a past generation had penetrated the surrounding mountains."[49] Time has not eroded the tradition, and many others since have emphasized the last spike as part of the exploits of men who conquered the wilderness. The official government plaque commemorating the last spike concludes, "A nebulous dream was a reality: an iron ribbon crossed Canada from sea to sea. . . . Here on November 7, 1885, a plain spike welded East to West."[50]

There is yet another strand to the legend of the CPR. Victorian popular beliefs held that the individual could make a real difference through the application of hard work and will. The myth of the CPR was a celebration of both the Protestant work ethic and the industrial revolution.[51] People like

Stephen, Hill and Van Horne were naturals for such a role. Daring to venture where others feared to go, they made themselves the most powerful businessmen in the land. They were the "captains of industry" who had carried through such an audacious act, who had triumphed over the doubters and the sceptics. They were the "men of vision" to undertake the task, to do it well and to complete it.[52] In their lives and characters they became archetypes, symbols of the values and morals of an age. William Van Horne was not just an exemplary railway builder but a paragon of hard work and morality. During the Chicago fire, it was recorded, he had risked life and limb to remove material from his company's offices. Then, black with soot, he returned home only to continue his heroic endeavours: "Reassuring himself of the well-being of his wife and her infant, he set to work very quietly and industriously to strip his home of everything, and more than everything, that could be spared." Bedding and clothing were then sent to "the shivering refugees from the South Side who were camped in the park."[53] In the more jaded world of the late 20th century the men of the Syndicate have stood up much better than most Victorian heroes. Their courage and competence seem to distinguish them from other old idols who were shoved aside as new sensibilities emerged.[54] Even in their less desirable attitudes the men of the Syndicate were romantic figures, "larger-than-life characters, who ruled with the kind of iron-fisted autocracy that may never again be possible."[55]

The adventure, the romance, the embodiment of hard work and even vision have all been assigned to the Canadian Pacific or its builders over the years. All of these characteristics are, however, merely embellishments upon the main symbolism of the railway — nationalism. As a CPR publication immodestly concluded in 1946, "All down the years Canada and the Canadian Pacific have marched ahead together. Indeed, to the world at large, the two have become synonymous."[56] Self-serving though such a company statement might be, it is also a reasonable claim. For in both the scholarly and the popular portrayal of the CPR, nationalism has loomed large. This nationalist image, moreover, has survived to the present and may explain much of the uneasiness about the decline of the most visible of all railway activities, passenger service.

The national connection is, of course, based upon historical fact. At the time, both the Government and the CPR recognized that annexation and settlement of the North West was impossible without a railway. Equally important, however, was the evolution of a particular geopolitical analysis of the nature of Canada. This viewpoint reinforced the premises behind the Canadian Pacific and became central to later popular as well as scholarly interpretations. This geographical aspect was summed up in its starkest form by the late 19th century intellectual Goldwin Smith. Canada, he said, was really "four separate projections of the cultivable and habitable part of the Continent into arctic waste."[57] For Smith such geographical realities meant that Canada's inevitable destiny was annexation to the United States. For most other observers the result wasn't that inevitable, but the difficulties posed by the geography of North America were central to the analysis of Canada as a national entity.

Few assessments of the Canadian economy and nation ignored Canada's distinct geographical regionalism. It was, however, the "staples school" of Canadian economists that turned physical reality into an elaborate and influential theory. Aspects of the theory were present in the works of pioneer political economist O. D. Skelton.[58] In the 1920s, W. A. Mackintosh of Queen's University and Harold Innis of the University of Toronto made the theme explicit. The massive research work of the Rowell-Sirois Commission (1937–41) drew upon the work of a generation fully imbued with these ideas and incorporated it into its own assessment of the Canadian nation.[59]

The staples thesis in its basic form posited that colonies grew to economic maturity through the exploitation of a series of staple products — furs, timber, wheat, minerals. Such staples, under certain conditions, provided the means for population growth, development of entrepreneurial skill, and capital formation. These things, in turn, permitted the development of a more complex economy. The formation and evolution of a staples economy were also seen to have a major role in national development. Commercial links developed in this manner determined imperial and then national boundaries. This was what explained Canada's separate existence in North America. The staples exploited through the centuries had been linked into an East-West trade system with Europe (and especially London) as the metropolis. This East-West system overrode the disuniting forces posed by geography and tied the regions together. In a famous phrase, Mackintosh said that Canada existed "in defiance of geography."[60] Innis, looking to the rivers as a precedent, disagreed, stating that it existed because of geography.[61] All economists of the staples school, however, felt that railways were the technological instrument that allowed the East-West trade flow to continue into the modern age.[62]

The distinctly unromantic prose of Innis and Mackintosh contained within it a dramatic historical theme. For in their interpretation the credit of creating and maintaining Canada went to those who in some way grasped the essential reality dictated by geography and shaped by national pride. Exploitation of staples wasn't just a matter of luck but of policy. Those who failed to understand or who deliberately stood in the way of the opportunities were seen as negative, narrow individuals, opposing destiny.[63] This was clearly sensed by those who, drawing upon the staples thesis, developed what became known as the "Laurentian Theme" of history.[64] Individuals with more flair for drama (and more readers) picked up the themes of Innis and Mackintosh and merged them with the long-standing romance associated with the CPR. Perhaps the best known of these individuals was Donald Creighton, the foremost historian of the years surrounding World War II. Creighton first picked up the vision of the east-west transcontinental vision from Innis, whom he much admired, and translated it into his own words in his 1937 work, *The Commercial Empire of the St. Lawrence.*[65] This work dealt with the years of furs and canals and thus predated the CPR. This was only the first part of the story as far as Creighton was concerned, however, and he brought the vision to fullest fruition in his masterful two-volume biography of John A. Macdonald. Macdonald and those who comprehended the vision of a transcontinental Canada became heroes. Confederation and the Canadian Pacific were made inseparable, and people like Stephen and Van Horne were idolized.[66] Creighton's work became classic, one of the best selling works of academic history ever written in Canada. As such it did much to reinforce and expand the association of the CPR with the national vision, especially as the work was published during a period of post-war nationalism and confidence.

Yet Creighton's readership pales when compared with that achieved by Pierre Berton's rendition of the CPR legend. Published in two volumes in 1970 and 1971, Berton's history of *The Great Railway* was a phenomenal success. In a country where a sale of 5,000 books can create a best-seller, his railway books sold more than 100,000 copies and are still in print. Furthermore, the works were later developed into a mini-series by the Canadian Broadcasting Corporation. Taking a romantic nationalist interpretation of Canadian history, Berton used a popular variant of the Laurentian school. Even the title of the first volume, *The National Dream,* summarized the symbolism of the railway:

> Macdonald's vision of Canada did not stop at the Great Lakes; his dream was of a transcontinental British nation in North America — a workable alternative to the United States. To achieve this dream, the railway was a necessity, or so the Prime Minister insisted: it would stitch the scattered provinces and empty territories of the West together, as the government-owned Intercolonial was intended to do in the east; . . . it would forestall American expansion; it would be the spine of empire, an Imperial highway linking the British Isles with the Orient and avoiding the appalling voyage around the Horn.[67]

Berton's books were so successful not just because of the popular name behind them or the readable prose. He has written many other books, before and since, and none have matched these in impact. What made them so remarkable was that he adopted a set of beliefs about Canadian development and about the importance of the railway to that development that was already firmly established in the Canadian mind. The fact that he wrote at a time when the national sentiment was still high in the wake of Expo 67 and at a time when railway passenger services seemed threatened simply accentuated the appeal.

Berton and Creighton have been singled out only because they are among the best known and best selling historians of the era. Numerous others could have been cited, and at some point a graduate thesis will dissect the components of Laurentian nationalism. What is important, however, is that a part of the standard wisdom of Canadian nationalism is that there is a close connection between the success of the railway and the triumph of the young Dominion. It is a lesson taught by the scholarly interpretations implicit in the national policy and staples thesis; it is taught in the textbooks of school children; and it is found in the many popular readings on railways. There is even the already-mentioned hit song by Gordon Lightfoot and an epic poem, "Towards the Last Spike," by E.J. Pratt. " 'No Road, No Union,' and the converse true / East-West against the north-south run of trade."[68]

The CPR has from the beginning recognized the marketing and political value of such an image and uses it whenever possible. It has even hired popular historians to recount the daring, the vision and of course the nationalism of the railway. For example, John Murray Gibbon's commissioned work, *Steel of Empire*, published in 1935, links the railway not only to Canadian nationalism but also to the age-old European dream of a connection to

China. The first chapters deal not with the CPR at all but with the long-standing search for a route to the East, the exploits of the fur traders, and other incidents in Canadian expansion across the continent. The message is clear. The CPR was not just the whim of some Confederation-era politicians but the culmination of a centuries-old dream.[69]

The nationalist imperatives that surrounded the construction of the Intercolonial and the CPR added a new dimension to the railway in the Canadian mind. From social or economic necessity it had now become a national necessity, even an icon. The additional elements of success, daring and romance only added to the appeal. For some Canadians the transcontinental links were a part of the Confederation package. Maritimers have long argued, for example, that the Intercolonial was "part and parcel of the contract of Confederation."[70] Even for Canadians who did not interpret provision of rail service as a quasi-constitutional arrangement, the railways and especially the Canadian Pacific were intimately connected with the founding of the nation. That connection was and is reinforced by the tremendous success of the project. Here in a dry, unemotional Confederation process was a heroic achievement on a world scale. The nationalist association, as we will see, spills over to all railways in Canada to a degree. The public's sense of attachment to railway travel, or to the possibility of railway travel, is very likely linked to their identification of successful, operating railways as a part of the national framework.

The railway now totally dominated land travel over any distance. In contrast, the development of roads languished. Indeed, as many later saw it, the emphasis on railways precluded any serious attention to roads. As a 1930s Ontario royal commission put it, "For many years they [roads] had been neglected in favour of the railways. . . ."[71] This echoed a theme that had been around for some time. In the late 19th century a group of citizens came together to complain about the state of roads: "Had railroading and navigation by steam been deferred for another half century, we would have been advanced farther in the science of road-making."[72]

Certainly the railway made the road even more marginal than it had been. For the railway was able to go inland, to penetrate beyond the headwaters and to go wherever sufficient commerce and passenger traffic existed. Railways became both the feeder systems to water and, as in the case of the Grand Trunk, competitors with waterways. Passengers travelling between cities now had a fast, year-round and comfortable means of travel. As the rail system developed throughout Eastern Canada from the 1850s to 1880s and Western Canada from the 1870s through early 1900s people had fewer reasons to travel any distance by road. Even in the neighbourhood of cities the road came under challenge. Commuter trains and their short-haul analogues like streetcars meant that rail travel became the basis for early commuting and suburbanization.

It is difficult to make too many generalizations during this era of neglect. Still, a few general points are apparent. First, the Dominion government had a very limited interest in the Canadian road system. Whereas other public works, namely the canals, had been declared to be for the national benefit under section 92 of the *British North America Act, 1867* and though railways became objects of national policy and large subsidies, roads were ignored. Second, among the provinces and territories, local administration was the rule. Roads were left to counties or their equivalents to maintain and improve. Statutory labour, local tax levies and rare provincial subsidies were the basis of a rudimentary, underfunded system, one that saw maintenance on all but the most major roads conducted in just a few short weeks every year.[73]

There was one exception to this general rule of indifference, though the exception is a spotty one. The federal government and some of the provinces were active on the frontiers of settlement. The development of colonization roads was a practice that predated Confederation and was continued for sometime thereafter in both Ontario and Quebec. Where crises of access developed, as during the British Columbia gold rush of the 1850s and 1860s or the Yukon gold rush of the late nineties, crash programs were often undertaken. When the effort was made the results could be impressive. Immediate imperatives in the 1860s saw the completion of the Dawson route, a mixed water-land route from the Lakehead to Manitoba, and the 385-mile (620 km) Yale Road, built to handle gold rush traffic in British Columbia.[74] Even in these exceptional instances, however, roads were viewed as poor substitutes for railways. Indeed, the assumption was that the road was a temporary measure, preparing the way for future railway development. The Dawson route was never thought to be a long-term solution and was abandoned after the CPR replaced it. It would be many decades before the Lakehead and Winnipeg were once again connected by road. Likewise, parts of the Yale Road were abandoned when the railway reached British Columbia. In the Yukon the boom times of the turn of the century brought immediate plans for the replacement of the rough trails inland with a railway.[75]

Finally, in contrast to the railways, roads played no part in the national imagination of 19th century Canada. They were, if a topic at all, one of complaint on a local level rather than of dreams at the national. This is reflected in the historiography. O. D. Skelton's book, *The General Economic History of Canada 1867–1912*, ignores roads.[76] As part of the massive 23-volume history of Canada published in 1914 by Adam Shortt and Arthur Doughty a special 112-page article on land transportation was commissioned. Roads got just over six pages of coverage before the article shifted to the really important story — railways.[77] Even as late as 1938 the standard study of transportation in Canada by G. P. de T. Glazebrook has nothing at all on roads between 1867 and 1900.[78] Every chapter in this book from Confederation to World War I has "Railway" in the title. Not until the 1960s, by which time the importance of roads had changed considerably, did anyone write anything significant about their history. As it is in history, so it was in the contemporary material: the monographs, government studies, public debates and other materials were mainly on railways or canals, not roads. Roads were referred to, of course, but only as incidents in travel memoirs — usually horrible, occasionally pleasant — and not as a significant element in the national vision. Roads remained at the margin of Canadian transportation policy between the arrival of the railway and the turn of the century.

## PASSENGER TRAFFIC AT THE TURN OF THE CENTURY

It is extremely difficult, except in the most rudimentary way, to distinguish between policy aimed at railway passengers and that aimed at railway freight before the late 19th century. In the minds of governments and companies, development was designed to encourage the transport of both. Yet it is likely that the romance attached to railways over the years applies more to passenger travel than to freight. An individual's sense of connection with the railway has much to do with memories of trips on the railway to visit relatives or friends or to take holidays. It may also have much to do with family history, with parents or grandparents whose life in Canada began with a railway trip. For many more the railway was until recently the primary tie to the outside world, connecting isolated rural communities to the larger centres. It is therefore crucial to explore the evolution of passenger policy and the passenger experience more closely. With the approach of the 20th century, railway and government policies changed, making it easier to trace this evolution.

Government involvement in railways was initially experimental and fluid, as might be expected: it was coming to grips with a new technology. Much of the pre-Confederation legislation was designed to control the financial and construction excesses of this powerful new form of corporation. Railway acts were concerned with destroyed animals, seized property, ruined fences. Legislation created a Board of Railway Commissioners to try to ensure railway compliance with the rules.[79] The railways, for their part, more or less did what they felt was necessary and then sought to present their case to government or the courts. In the actual operation of the railway, however, initial government activity was limited to two general areas. First, there were rules on passenger safety, an understandable intervention given the horrendous accidents that began to occur as soon as railways began operating in the 1850s. Second, there were rules to prevent discrimination, drawn from British precedent of the railways as "common carriers." Under this principle all people are offered similar services at similar prices.

With Confederation, colonial precedents were carried forward. In particular, the concept of the common carrier was now well established, and the Railway Committee of the Privy Council was established under the 1868 *Railway Act* to oversee railway activities. This body of appointed politicians had the responsibility for everything from rules of signage to right-of-way privileges. Also within its ambit were rules for the safety and comfort of passengers. The committee was far from ideal as a means of railway regulation. It had neither the staff nor the expertise to undertake detailed investigations. Nor did it always comprehend the implications of the decisions it made. This was also an age of laissez-faire, and the tradition of regulating the common carrier contended with a desire to leave private business alone. Still, by the time the committee went out of business in 1903, a considerable body of statutes and regulations on passenger transport had evolved in Canada. The most important elements of these were incorporated into the new *Canadian Railway Act* (3 Edw. 7, c. 58). The Act also gave the newly appointed Board of Railway Commissioners power over such passenger issues as standards of the railway station, the conductor's right to expel passengers and various safety measures. Further, in a precedent that could, if extended, apply to line continuation, the Act gave the Commissioners the right to set tolls and to force trains to alter schedules to assist passengers in making connections between different corporations (s. 284). Thus, as early as 1903, the doctrine of the common carrier contained within it the principle that railway operations, and presumably profitability, could be intruded upon in the interest of not only public safety but also public convenience.

Parallel to this was a growing effort by the railways to attract passenger traffic. From the beginning the CPR understood both the dollar value and, perhaps more importantly, the positive publicity that went with satisfied tourists. The West was still the frontier, and the promise of good hunting and dramatic sightseeing and the opportunity to meet real Indians and cowboys attracted tourists from more eastern lands. In the years immediately after the completion of the railway it became common practice for affluent British tourists to make the trek across Canada and write about their experiences. The authors naturally sought, with greater or lesser skills, to convey a sense of romance and adventure, which only added to the aura of the Canadian railway adventure.[80] In the East the Canadian Pacific and the Grand Trunk issued guidebooks that talked of the glories of Niagara Falls or of fishing in New Brunswick.[81] More will be said about the tourist trade below, for, although it was a growing part of the railway business, it was not until later that it became really important.

Success in passenger traffic as far as the CPR was concerned depended upon immigrants to the West and the spin-off traffic that resulted from their homesteading efforts. Between 1881 and 1914 the Prairie population increased from just over a quarter of a million to more than 1.3 million. It was the Canadian Pacific that brought most of these people westward. In the first full year of operation the line carried more than one and a half million passengers. By the early 1890s the figure had doubled to more than three million. When the wheat boom hit the Prairies at the turn of the century the numbers continued to rise, to more than four, then five, then seven million. By 1913, the last year of the boom, the CPR carried more than 12 million paying passengers.[82] To handle this traffic the railway built special immigrant cars, advertised in Europe and arranged through journeys at cheap rates. And because they owned vast tracts of Prairie land as a result of earlier grants, the railways could run a service that handled the immigrants' needs from the time they embarked in Europe until they were settled on the land. It was a nicely integrated relationship. That original passenger trip could lead to land-sale revenue, and that sale could, within a couple of years, lead to increased freight traffic as crops were exported and goods imported. Throughout the West the increasing population brought an ever larger number of commercial passengers to Prairie towns and cities. Thus the original cheap immigrant fare, profitable in itself, was repaid in many ways over the years that followed.

Obviously not all passenger traffic depended upon immigrants. In the East, where both the CPR and the Grand Trunk were major systems, the traffic was different. Most of the people using the trains were making round trips. Their trips were shorter and often involved major urban centres like Toronto, Montreal or Halifax. People might be travelling for business, for holidays or for visits with relatives. In many cases the passengers were commuters, travelling short distances from satellite communities to business in the city. Even in the West the nature of passenger traffic was evolving. In the first decades the immigrant traffic was central to Canadian Pacific's passenger totals. By the early 20th century the immigrant traffic was complemented by the more routine business and personal traffic typical of the East. Still, before World War I, immigration remained important to CPR's passenger system.

Whatever the purpose of the trip, the fact was that for the late Victorian Canadian, train travel was the norm. Thomas Keefer may have been melodramatic in his predictions of the benefits of the train, but for the public the train did have many emotional associations. It was the train that brought the settler and his family to a new life. It was the train that took relatives to visit one another, and it was the train that provided access to the outside world. The national symbols, in other words, were not remote and distant but a part of the daily rhythm of existence. Even after half a century nothing was more commonly used as a symbol of industrial progress. Only electricity, just beginning to make its appearance at the turn of the century, could even come close.

It is possible, therefore, to talk by the late 19th century of a relatively mature railway system. As Figures 3 to 6, which are reproductions of the original maps, indicate, coverage was excellent through central Canada, good in the Maritimes and, though far from satisfactory, increasing yearly in the West. The great projects of Confederation were complete, and the public already viewed their railways as an integral part of both the Empire and the nation. Government relationships to railways were fairly well established.

Governments would aid railway development, often considerably. At the same time government, whether Dominion or provincial, had generally resisted direct ownership. There were the exceptions of the Intercolonial and Prince Edward Island systems. The ongoing operational losses of the two railways, however, generally reinforced rather than challenged the Government's desire to stay away from ownership.

All in all the procedure of land and cash had not worked badly, though the landscape was littered with charters that had been abandoned and offers of land grants that had not been fulfilled. Now, as Canada began the period of greatest expansion in its history, the final great phase of railway expansion was about to begin. Ultimately this expansion would bring the old subsidy program crashing down and forced into creation a network of nationally owned and operated railways.

## THE FINAL PHASE OF RAILWAY DEVELOPMENT: 1897–1917

Once again the prize was the West. After 1896, international economic conditions improved. Canada, especially the West, became the destination of choice for thousands upon thousands of immigrants (see Figure 7). Higher wheat prices also provided a rapidly growing export product. Reinforcing these trends was the inflow of British capital to the region. The long-anticipated Western boom was under way, and it continued almost uninterrupted for nearly 15 years. In the 1880s it seemed foolish and daring to talk of one transcontinental railway; now it was feasible to talk of two or even three. The relative stability of the railway system was about to be shaken as the Dominion entered the third and last phase of great railway expansion.

Forces in the West and the East had reasons to want railway expansion. After two decades of CPR monopoly many westerners were disgruntled with high freight rates and with CPR caution in expanding its branch-line network. Two railway entrepreneurs, William Mackenzie and Donald Mann, responded to the disgruntlement and to the profitable charters lying around by constructing a growing pattern of local lines around Winnipeg in the 1890s.[83] By the turn of the century their ambitions had grown, and preparations were under way to expand their line, now known as the Northern Railway, eastward to the Lakehead. There was even talk of heading westward toward the Rockies. For Prairie farmers dependent on the CPR such competition was a welcome thing, and they encouraged their legislatures and the company to move forward with the plan.

*Figure 7*

***NUMBER OF IMMIGRANTS TO CANADA BY YEAR, 1885–1914***

In the East it was not regional grievances that were emphasized but the opportunity to make up for a squandered past. The Grand Trunk railway had in the 1870s refused to build an all-Canadian transcontinental line and had therefore been relegated to the sidelines as the CPR became one of the world's most famous railways and was even profitable. The Grand Trunk not only missed the opportunity to become a transcontinental but over the decades since the CPR's completion had been forced to wage an often vicious competition in the East with this upstart rival. Now the Prairie market seemed for the first time capable of supporting a second transcontinental, and the Grand Trunk was determined not to be left behind again.

Both railways followed the established pattern and turned to governments for support. The details of the subsidies, as is so often the case, are extremely complex and only of marginal relevance here. What is important is that a combination of politics, stubbornness and too much optimism meant that instead of choosing between one of the rivals for the new transcontinental line, Canada got both. Initially the Grand Trunk, along with its newly created subsidiary, the Grand Trunk Pacific, was the favoured child of Prime Minister Wilfrid Laurier's Liberal government. Large subsidies were handed out, and the Government even agreed to construct the most unprofitable portion of the line (north of the Great Lakes) and then turn it over to the completed railway. The Northern Railway refused to back off, however, and used its considerable clout in the West to gain local support, including significant grants and guarantees from provincial legislatures. Then, when Robert Borden's Conservative party took power in 1911 the Northern was able to join the Grand Trunk at the federal trough.[84]

For the next several years the two railways proceeded to build lines across the Prairies along the old Yellowhead route. By 1907 they were in Edmonton, and both were determined to push through lines to the West coast that were, in many cases, practically next to each other. Government largesse, excessive optimism and business egos led to one of the greatest bursts of railway expansion in history. Prairie mileage had tripled to some 11,000 miles (17,700 km) by the eve of World War I. Overall, by 1915, as Michael Bliss has pointed out, Canada was the nation with "more railways per capita than any country in the world."[85]

These railways had been built at considerable expense to the Canadian taxpayer. As a matter of pride and public relations the railways sought to capture the public imagination as the CPR had done. The Northern Railway had the more authentic claim in this regard. With some justification it portrayed itself as the corporate entity that would finally rescue the western Prairies from CPR monopoly. This was the "West's own railway," which by its very existence would force the CPR to be more competitive in rates.[86] This belief was important both in the political support the Northern gained during its rapid expansion and in the considerable financial support given to it by western provinces like Manitoba. If the CPR capitalized upon the ideal of national unity, the Northern capitalized upon a sense of regional grievance.

The Grand Trunk and Grand Trunk Pacific had a more difficult time attaching themselves to the romance of Canadian railroading. The railway did have a positive image for good service in the East. It was an unknown in the West, however, and the seemingly rich deal it struck with Laurier's government to compete with the Northern did not endear it to Westerners. The railway's managers did take a leaf from the CPR and supported a book extolling the virtues of the project. Its author looked to the imagery of both the Northern and the Canadian Pacific and made up in rhetoric what the Grand Trunk Pacific lacked in historical tradition. The Grand Trunk Pacific would take on the CPR, which "wielded its power in an autocratic manner." Once completed the "farmer would no longer be at the mercy of a railway octopus." The people who accomplished such works were, of course, heroes:

> When the Epic of the railway is written, the men who laid the foundations of the National Transcontinental will loom prominently therein. . . . They were not communicative; hardship, privation, peril, and sensational excitement had been encountered so frequently that they considered such a part of the daily round, and now that they could view them from afar, and a more distant date, they made light of them. But when I probed beneath the surface, as seated round the blazing fire in the lonely camp in the wilderness I drew them into conversation, and once more threw them back into the days when they were up in the forest toiling mighty hard to find that four-tenths of 1 per cent grade, they grew slightly reminiscent. And what stories they could tell! What thrills they could give![87]

Despite this author's enthusiasm, the "Epic" was never written. The Grand Trunk railway, though extremely well built, was never able to assert a romantic public image. Even the Northern, though supported by Westerners initially, found its own image floundering within a few years. For what these two railways conjured up in the public mind was not the romance of construction or even the opening of new districts but the sheer cost. Indeed, their experiences shifted the whole image of the railway in Canada generally. Before the new transcontinentals were built the public still revelled in the Victorian imagery of the railways as a symbol of progress and technological triumph. The expectation was that railway construction and expansion were a part of Canada's future. Even among Westerners who distrusted the CPR, for example, there was a continuous clamour that that railway build new branch lines. After the experience of the new transcontinentals the image shifted. Railways became associated with their costs as much as their results. The excesses of the early 20th century meant that henceforth both public and political attitudes to railway development would be much more cautious, even negative.

What happened in the interval is extremely complex. The business affairs of the Grand Trunk and Northern were a massive tangle of land grants, Dominion and provincial government arrangements, bank loans, share issues and holding companies. Amidst all the confusion, however, the story is actually fairly straightforward. First, the railways and the Government overestimated the ability of the nation to support a massively expensive new transcontinental line. Certainly they overestimated its ability to support two such lines. Second, the Government found itself drawn into the same sort of position it had experienced with the canals three quarters of a century before. Loans, subsidies and especially loan guarantees made the Government hostage to the railways. Even before World War I broke out, for example, the Dominion government had acquired some $40 million in Northern Railway stock, and that was only a fraction of the amount they had loaned out. The railways simply could not be allowed to go under. This was especially true because at least one province (Manitoba) and one bank (Bank of Commerce) were so heavily committed to the railways that their bankruptcy would have followed that of the railways almost immediately. Third, this overextension of resources was made much worse by World War I. A wartime economy pushed prices up rapidly. The costs of supplies, of locomotives and of labour all increased. At the same time the traditional source of foreign capital, the London money market, dried up in the face of wartime demands at home. By 1915 the Northern was effectively bankrupt. The Grand Trunk Pacific was not far behind.[88]

The Government sought answers to the chaos through a royal commission.[89] The Drayton-Acworth Commission was split ideologically. One faction hoped that a merger of the two railways might allow a continuation of the system in private hands. The other side, and ultimately the Government as well, saw this as unrealistic. The fact was that most of the railway funding, to the tune of a quarter of a billion dollars, was tied to government support.[90] To put this in perspective, the total revenue of the Canadian government on the eve of the war had been only $169 million. At the provincial level, British Columbia had guaranteed $40 million of Northern debt, and Manitoba had guaranteed $25 million. The annual revenues of the two provinces were, respectively, $10.2 and $4.1 million (1913 figures).[91] There was thus no real choice. The federal government decided in 1917 to nationalize the two railways.

The nationalization process was almost as complex as the financial freewheeling that made it necessary. It was 1923 before the Government railways — the Prince Edward Island Railway, Intercolonial, Grand Trunk and Grand Trunk Pacific, Northern, as well as smaller railways — were formally amalgamated into the Canadian National Railway (CNR) system.[92] The Canadian government, which had for so long resisted any massive ownership of railways, now possessed nearly 22,000 miles (35,400 km) of track and a massive corporation, spanning a continent and employing nearly 100,000 people. It had also assumed a massive debt and, in a controversial move, put that debt on the books of the new Canadian National corporation. Thus CNR began life with long-term debts of nearly $2 billion! This made deficits inevitable, and these would be a harsh reminder of the nature of its birth. "The mood of the time in which Canadian National Railways were born was more critical than sentimental; more conscious of the burden that was to be carried than of the ambitions that had been foiled; more censorious of the sins of the fading companies than proud of the achievements they had made."[93] The Canadian railway system was, to all intents and purposes, complete.

## 4. THE "MATURE" RAILWAY SYSTEM AND THE RISE OF THE CAR CULTURE: 1900–1945

Now that the railway system was in place, what did it mean in terms of passenger service? How much was the railway a part of the everyday life of the Canadian? In general terms, the railway network, so overbuilt from a financial point of view, gave the public good access in most settled parts of the nation. In the cities and larger towns, conveyance to the solid brick or stone railway station could often be made by public vehicle. In the larger cities street railways ran regularly along major thoroughfares. The traveller could therefore leave a house in Toronto, Montreal or elsewhere, walk to the corner and catch a street railway to the railroad station. Many passengers took their horse and buggy or, occasionally, went in the new device, the car. Outside the cities, of course, private transportation was all that was available.

In city or country, however, the destination was the train station. For it was there that connections to the outside world were made. In an era before competition, the station combined the role played by air terminal, bus terminal and, of course, train station today. As the architecture of Union Station in Toronto (completed 1927) indicates, the stations themselves were opulent affairs, reflecting the power and substance of the railway's dominance over the nation's transportation network. The stations were, as the slogan of the time had it, "the crossroads of commerce."

This was more than an idle boast. The major stations were central to business and personal travel. At the major stations scores of trains departed daily.

Once in the station the passenger had access to the continent. Complex routings along different lines and different railways created a wide variety of choices of routes, destinations and levels of comfort. Indeed, the complexity and variety of the turn of the century timetables are more than normally striking for the contrast they present to the current atrophied state of passenger rail service in North America. Also striking and occasionally forgotten amidst the nationalist symbolism was the vast amount of railroad service to the United States. The Canadian Pacific and Grand Trunk both had regular service to all northern U.S. centres. For more distant points they provided transfers and through connections via U.S. lines.[94]

The passenger taking a long trip also had a number of options for sleeping accommodation. The Pullman sleeping car, developed in the United States, was widely used. Canadian Pacific even boasted that it had improved the Pullman and provided comfort superior to that of any U.S. line. The sleeper was also available in a series of classes. First class was a luxurious service, designed to attract the affluent family and business traveller. The tourist sleeper was less ornate but was only about half the cost of first-class accommodation. There was also the colonist sleeper, though the average intercity traveller was unlikely to use or even see this accommodation.[95] It was really designed for the special immigrant trains that had been so important before World War I.

Also, well before the 1920s, dining cars had become common. Earlier it had been normal for railways to schedule station stops so that passengers might eat — much as bus lines do today. Some of the CPR's first hotels in the Rockies, such as Mount Stephen House, were in fact way stations. The schedules did not leave people much time for a leisurely lunch. Twenty-minute to half-hour stops were considered adequate.[96] Such tight timing led to discomfort for passengers and undoubtedly delays for the crew. By the

20th century, however, the well-appointed dining car was one of the features expected by first-class passengers. These cars rarely made money for the railways, but they were a necessary service if railways were to compete. On longer trips and the most important lines, therefore, dining service was regularly available.

There were some alternatives to trains. On the Great Lakes and along the British Columbia coast, travellers could take steamships, many of them owned by CPR and integrated into train schedules.[97] For other trips people could simply travel by horseback, carriage or car. Such individual travel is impossible to measure, but over long distances it was certainly an inferior means of getting about. Nothing, however, could compete with the train, which completely dominated both commuter traffic and the long haul. In 1920 there were six train trips taken for every man, woman and child in Canada.[98] Fifty years later it was less than one — and the relative cost of train tickets had decreased in the interval. In the years between the turn of the century and the Great Depression, the normal business or personal traveller almost certainly took the train to travel between cities.

To maintain their dominant position after the war, however, the railways did have to develop new strategies. Before World War I, as has been discussed, two types of passenger predominated: the local commuter (mainly in Eastern Canada) and the immigrant. Though the train was a part of the rhythm of life, it was also a means to other unrelated activities — settlement, business or visits. By the 1920s, however, there were growing concerns about the future of both kinds of traffic. Most of that concern was focussed on the apparent end of massive immigration to Canada. Before World War I, immigration had reached historic highs, averaging more than a quarter of a million people a year. Naturally, the war brought a precipitous decline: immigration reached a low of 36,000 in 1915. More significantly, the recovery after the war was incomplete. The days of the "last best West" as a major destination for immigrants was over. Canada's primary agriculture frontier was now taken. This, combined with more restrictive rules, meant that half as many immigrants came to Canada in the 1920s as before the war. With a larger percentage of these staying in the urban areas of the East, immigrants could not provide the staple passenger traffic for the railways that they once had.[99] If the immigrants weren't coming in as great numbers, however, the railways hoped that the tourists would. In the 1920s the railways put a major effort into attracting the lucrative tourist dollar.

Tourism was not new to the railways. From the beginning the Canadian Pacific had made efforts to draw tourists to the West. Passenger agents in London and the United States, although concerned primarily with immigrants, distributed promotional pamphlets emphasizing the grandeur of the scenery and the comfort of the railway.[100] William Van Horne himself liked to make up advertising slogans, though they were noted more for their unusual nature than their staying power. The railways also gave free passage or other support to well-heeled travellers who intended to publish their experiences.

From the beginning the railways had tried to sell more than mere railway fares to tourists. As land sales attracted immigrants, so an integrated CPR package could attract tourists. By 1886, one year after the railway opened, there were three hotel dining stops in the mountains.[101] The next year, with the active encouragement of the CPR, Banff National Park was created by the Dominion government. The CPR quickly built a hotel on the site, and in 1888 the first version of the Banff Springs Hotel opened for business. By 1891 it was receiving more than 3,000 guests a year, almost all arriving by railway. Over the next decades the network was improved and extended. The "Chalet" Lake Louise (1890)[102] and Hotel Vancouver (1887) reinforced the network of hotels and emphasized the fact that tourism for the CPR increasingly focussed on the mountains. By the turn of the century the fare-paying passenger had an annotated timetable to describe local sites, several luxurious hotels at which to stop over, and possible side trips and excursions at various points along the way. There were also 115 sleeping cars to cater to the luxury, largely tourist, trade.[103]

All of this paled next to the efforts of the 1920s. The two railway companies made massive investments in the tourist industry. As one historian has said, "the hotel and resort war that took place in the later twenties cannot be explained by rational projections of expected profits."[104] It can be understood, however, by realizing that for the first time two complete transcontinental systems sought supremacy. Each resented the other, and both were led by determined, energetic individuals. Accordingly, millions of dollars were spent on constructing or renovating hotels still familiar today: the Bessborough in Saskatoon, the Nova Scotian in Halifax, the Chateau Frontenac in Quebec City and the Chateau Laurier in Ottawa. And in Toronto, Canadian Pacific built what was supposedly the largest hotel in the British Empire, the Royal York.[105] At $16.5 million it cost more than the annual revenue of six of Canada's provinces! Of course these hotels were for business travellers as well as tourists. They were also a part of the railway's image, an image that would be increasingly difficult to maintain when the Great Depression hit within a few years.

Despite all these expenditures, the railways continued to focus their efforts for the tourist dollar in the mountains. By the 1920s the earlier facilities at Banff and Lake Louise had grown in size and splendour. To the north the Canadian National Railway built Jasper Park Lodge (1922). Along the CPR route through Banff, detailed guidebooks were available. These not only told you of the sites to be seen but all the activities that could be arranged as a part of your trip. Some of this was tremendously organized. It was possible, for example, to detrain at Banff, meet a prearranged guide, tour Banff, travel to Lake Louise ("a fire proof and modern hotel with accommodation for seven hundred guests"), spend the night there, get up in the morning for a motor trip to Emerald Lake and then go on to meet the train. The cost was $18.50.[106] Side trips were also possible at various sites in British Columbia.

Around the major cities of the country, railways provided another type of tourist service. From the 1890s on, the growing urban population of Canada, especially in Ontario and Quebec, had begun the ritual of escape to cottage country. Private cottages or resorts dotted along the Laurentian and Muskoka lakes created a lucrative market for trains. Even by the early 1920s cars were still relatively rare and a 100-mile (160 km) trip enough of an adventure that the trains captured a good deal of the trade. By the end of the decade, however, the car was beginning to have an effect on this trade.

Tourism was important not just for the railway revenues but for the way in which it further integrated the railways into the life of Canadians. Earlier sightseeing and adventuring across the wild West had now been replaced by a more sedate, widespread and family-oriented tourist trade. The grand railway hotels added to the glamour and romance of the railway system. The railways accordingly became associated with both the Canadian landscape and Canadian social activities — whether dining in the major urban hotels or backpacking in the Rockies. All of this added to the belief in the importance of the railway passenger system to the country as a whole.

Tourism and the increasing travel of the urban business class made the 1920s generally good years for the two major railway systems. Freight revenue was high, but so too was passenger traffic. In 1920 more than 50 million passengers were carried on the railway system, an all-time high. Throughout the 1920s numbers well in excess of 40 million were common. Moreover, revenue for passenger traffic per train-mile increased in real terms throughout the 1920s. Overall, passenger revenue was an important part of the earnings of both CPR and CNR. In 1925, for example, CNR earned 19 percent of all revenue from passenger fares.[107] In contrast, 40 years later it would be 7 percent.[108]

The importance of these revenues was reflected in the service. Both major railways had more extensive passenger schedules in the 1920s than they had before or would after. The tourist who wanted to go westward from Calgary to Vancouver, for example, had a choice of four trains daily.[109] By the end of the decade the CNR had inaugurated a train that travelled from Toronto to Montreal in six hours. Even on the less popular runs the service was impressively complete and efficient. Many trains stopped at literally hundreds of communities while wending their way from one major centre to the next. Moreover, though major new routes were not opened in the 1920s, there had been continued construction of branch lines, especially on the Prairies. Thus despite of some closures and rationalizations resulting from the collapse of the Grand Trunk and the Northern, railway mileage in Canada increased by some 3,000 miles (4,800 km) in the course of the decade.[110] By that point most communities of any size in Canada outside of the North had access to a railway. At the end of the decade the train remained the common means of travel and a part of the ordinary daily routine and the special occasions of Canadians' lives. The railways remained king of passenger conveyance and passengers remained important to the railways.

## THE RISE OF THE CAR CULTURE AND ITS CONSEQUENCES: 1900–1929

Even as the railway system matured a new technology was rising to challenge the dominance of the railway. In the 30 years after the turn of the century the car would revolutionize Canadian life. Government attention would turn increasingly from the overbuilt and expensive railway system to roads. The public itself, though far from abandoning the railway, found the car's flexibility and privacy tempting. Though another generation would pass before the car overwhelmed the railway as a vehicle for passenger service, the changes that took place within a generation were, nonetheless, spectacular.

At the turn of the century the car was still a toy, owned by only a handful of Canadians. Indeed, the first Canadian car would not be built until the next year. None of the legal structures, roads or governmental financial systems were designed with any thought of the car. There were no licensing provisions. In fact there were no rules at all except those that could easily be borrowed from statutes aimed at horse and carriage. In one generation all this changed. After the turn of the century the car became an increasingly common sight on Canadian streets. By 1914 there were more than 50,000 vehicles registered in Canada.[111] In the 1920s ownership exploded, turning the automobile into an everyday form of transportation for millions of Canadians. By the end of the decade Canada had the second highest per capita ownership of motor vehicles in the world, more than double the rate of the United Kingdom or France. The legal, cultural, governmental and fiscal structures of the nation had had to adapt to this new technology. Along the way the basic form of the modern Canadian road system and road policies emerged. Sometime in the period between 1900 and the later 1920s the car became a fundamental part of Canadian transportation.

There was no single inventor of the automobile. Rather, from the time of the industrial revolution people had tried to harness motorized power to the carriage. It was not until the 1890s, though, that the car was distinguishable as a new vehicle, though the technology remained primitive. Shortly after the turn of the century cars were numerous enough that laws began to appear on the books to deal with them. This was especially necessary in the United States, which was rapidly becoming the world's most motorized society. As early as 1901 New York State passed driving regulations and laws, and by 1905 most states had speed limits.[112]

Canada was not far behind. Like the United States it had a prosperous population with large disposable incomes. Canadians also had obvious reasons for being interested in improvements in transportation, given the size of the country. Also, except for a few areas, Canada was thinly settled and that meant that fixed forms of transportation like the railway could not possibly serve every community. A land vehicle freed from the track but able to achieve relatively high speeds possessed great potential for a geography like Canada's. Thus, living next to the United States, prosperous in its own right and with a real need for transportation innovation, Canada soon followed American footsteps into the automobile market.

The first Canadian car was built in 1901 by the T. A. Russell Company. Before long other entrepreneurs and innovative carriage makers followed suit. A competitive and as yet only loosely formed auto industry soon developed, mainly in Ontario. Ontario was also the province where the car was first seen with any regularity. In 1907, the first year for which statistics of car ownership are available, Ontario accounted for more than 70 percent of cars nationwide. Outside of the Windsor–Montreal corridor and the Vancouver–Victoria area, car ownership was still extremely rare. Only in this corridor were there sufficient wealth, population and, not incidentally, passable roads to encourage any sort of car ownership.

Even at this early date, however, the rise of the car had forced governments to respond. Ontario passed a registration provision in 1904, and within a few years other provinces followed suit.[113] New technology also brought new rules of the road. The car operated at high speeds compared with horse and carriage, and this created concerns about safety. Accordingly, it was not long before traffic violations and traffic accidents became an item of concern. Speed limits (usually 15 to 25 miles per hour (24 to 40 km/h)), regulatory codes and lists of fines and punishments became necessary. Only in Prince Edward Island was all this legislative activity muted. That province resolved the whole issue by prohibiting motor vehicles outright. Even when, in 1913, it decided to allow motor vehicles the province was hardly enthusiastic. Driving was banned Tuesday, Friday, Saturday and Sunday. Perhaps it is not surprising that the province had a mere 31 cars by the beginning of World War I.[114]

As society came to grips with the new technology, auto makers continued to improve their craft. Companies collapsed and new ones arose. Giants like Ford and Buick and Oldsmobile began to take a larger share of the market. The open car gave way increasingly to the closed one — a very practical development given Canadian winters. Air-cooled engines gave way to water-cooled ones. Steam engines yielded to gasoline engines. Horsepower increased, and at the top end of the market considerable elegance was possible. There was also tremendous development of ancillary industries. Parts became increasingly available, as did gasoline and service.

Most important of all, however, was the arrival of the relatively cheap and reliable car. In 1905 the average price paid for a car was in the neighbourhood of $1,784, or about 18-months' salary for a middle-class white-collar worker.[115] Then, in one of the events that has become a legendary myth of industrial history, Henry Ford revolutionized production and design to produce the famous Model-T in 1908. Powered by a four-cylinder, 20-horsepower gasoline engine, the Model-T provided reliable transportation for $850. By the early 1920s up to a million Model-Ts were being sold every year in North America. Other companies quickly adjusted or, if they did not, sank into bankruptcy. By the 1920s several cars, such as Chevrolet, could reasonably claim price parity with the Model-T and superiority in design and comfort. The Model-T and its direct competitors made the car available to the middle class.[116]

These innovations accelerated the rate at which car ownership increased in Canada. As Table 1 indicates, the number of Canadian-owned vehicles in 1907 (2,130) had increased tenfold to 21,519 by 1911, and this number had more than tripled (69,598) by the beginning of World War I. Also, ownership had spread more evenly through Canada. Ontario drivers then owned less than a third of Canadian vehicles, and even Prince Edward Island had eased its anti-car position by World War I. As we saw above, it possessed 31 vehicles. The car had become a national institution.[117]

*Table 1*
AUTOMOBILE REGISTRATIONS, 1907–1929

| Year | Number | Year | Number | Year | Number |
|---|---|---|---|---|---|
| 1907 | 2,130 | 1916 | 123,464 | 1926 | 728,005 |
| 1908 | 3,033 | 1917 | 197,799 | 1927 | 836,794 |
| 1909 | 4,763 | 1918 | 275,746 | 1928 | 945,672 |
| 1910 | 8,967 | 1919 | 341,316 | 1929 | 1,070,664 |
| 1911 | 21,519 | 1920 | 407,064 | | |
| 1912 | 34,136 | 1921 | 465,378 | | |
| 1913 | 50,558 | 1923 | 513,821 | | |
| 1914 | 69,598 | 1924 | 586,850 | | |
| 1915 | 89,944 | 1925 | 652,121 | | |

**Source: Statistics Canada (formerly Dominion Bureau of Statistics), *Canada Year Book*, 1933, p. 686.**

The real boom was yet to come. In 1918 the Mayor of Hamilton, surveying the likely demands of the post-war world, warned "This is not the time of railroads, but this is the time of good roads, and it is the time of automobiles. The traffic conditions have absolutely changed during the past few years."[118] Despite the recent collapse of the Grand Trunk and Northern it was far too early to sing the death knell of the Canadian railway. Nevertheless, the Mayor had recognized an important point. The post-war world was car crazy. Even in 1921, when a vicious slump devastated many sectors of the Canadian economy, both automobile registrations and production continued upward! The Mayor was right. The time of the car had arrived.

James Flink, in his assessment of American automobile development, uses the term "car culture" to emphasize the pervasive influence the automobile has had on modern life. The car, Flink argues, "more profoundly influenced twentieth-century American historical development than the collectivity of reforms emerging from the so-called Progressive Era and the New Deal combined."[119] At some point the car became a sufficiently powerful presence that society began to revolve around it in myriad ways — from town planning to advertising to the economy. Thereafter nothing would ever be the same, and the arrival of the car culture, as much as World War I might be taken as the true end of the 19th century.

For Canada the car culture arrived in the 1920s. Whether judged by the diffusion of the technology, form of production or supporting infrastructure, the 1920s was a watershed decade for the car in Canada. The number of registrations rose to more than one million, and the number of persons per car dropped from 30 to 10. Throughout the decade registrations increased at an average rate of well over 10 percent a year. At the same time the horse declined in numbers for the first time since statistics had been kept. It would not recover.[120] On the production side, automobile manufacturing underwent a major series of consolidations, including the collapse of the last independent Canadian manufacturers by mid-decade.[121] It was also in these years that many of the modern distribution, marketing and advertising techniques associated with the car came into being. The development of the car culture also saw the formation of a more effective infrastructure. Automobile clubs, which had been irregular and largely local before the war, were expanded and organized. Likewise, anomalies in driving regulations (such as left-side driving) disappeared. Only one out of 10 Canadians may have owned a car, but the values of the automobile, its appeal to people and therefore its demands upon governments were far greater. The car culture had become a way of life.

The modern image of the car is ambivalent. Traditional images of romance compete with fears of pollution and safety. So it has been from the beginning. Carriage drivers protested against the fright to their horses caused by the noise and speed of cars. The absence of driving tests and the basically dangerous nature of the vehicle quickly made traffic accidents an issue. Given these decidedly mixed reviews, the striking thing is the hold the car had on imaginations, even by the 1920s. This was not just a new appliance such as, say, the electric range, but a new experience, and the imagery of that experience must be understood if the place of the car in 20th century Canada is to be understood.

There is a fact that precedes the mythology, however. The automobile was an improvement over the horse, not just in personal but in social terms. The concept of *The Horseless Age*, as one American automobile journal was entitled, was appealing for many reasons. When the car was introduced it appeared to possess considerable sanitary and social advantages over the horse. The horse was an animal and that created obvious problems. In New York City, for example, about 1,250 tons (1,130 tonnes) of horse manure was removed each year. There were also thousands of horses found abandoned or dead by city officials annually. Both the refuse and the carcasses created horrendous odour and health problems. Horses also got ill, often with infectious diseases that threatened surrounding animal life and caused suffering for the animal. At least when a car broke down it did so in mechanical solitude. In sum then, the automobile was "cleaner, safer, more reliable and more economical than the horse."[122]

The image of the car has never rested on such mundane matters as health and economy, however. Practically from the beginning, enthusiasts attached a whole host of values to the car. Before long it had developed a mystique of its own. Sometimes this mystique could be expressed in terms as romantic and all-encompassing as those used by early promoters of the railroad. Chevrolet advertised its cars under the banner headline, "What Transportation Means to Civilization." Civilization, it determined, was the result of the interchange of individual thought, "and that thought could only be exchanged if transportation was available." The car was the superior form of transportation because "it is not limited to mass movements nor [sic] fixed routes" but could penetrate everywhere. It was, accordingly, the great civilizer of the modern age.[123] This was a common theme in the advertising, but it was far from restricted to advertising. W. H. Dandurand of Montreal, one of the foremost early car enthusiasts of Canada, sounded reminiscent of 19th century railway philosopher Thomas Keefer as he described what improvement of a highway did for the region south of Montreal: "The schools are kept in good shape, the children are better dressed, the little girls wear new dresses and all the children wear boots. . . . Last year we noticed that they had flowers on their lawns and that they had real lawns on which they used lawn mowers and kept the grass nicely cut."[124] All this because the car could now readily traverse the area.

Such hyperbolic rhetoric points to an important theme of the age. This was a time of rapid urbanization. People feared that the movement to the city would undermine a moral fabric that, it was believed, rested in the countryside. The car provided a partial remedy to the problem. Rural families might be less tempted to throw their lot in with the cities if they were less isolated. The car provided an easy access from farm to city. On the other side, those who had already cast their lot with the city might at least escape the oppressive weight of concrete and brick to return to the countryside. Henry Ford summed it up with the comment "We shall solve the city problem by leaving the city."[125] The President of the University of Toronto, Robert Falconer, said much the same thing in 1915: "Is it not going to be possible to get people from the cities out into the country? Is it not possible to relieve the pressures of the cities?"[126]

These broad social values only indirectly translated to a personal appeal to the would-be car buyer and driver. In selling the car, advertisers used themes of status, taste, refinement and culture. Many of the themes would still be familiar today. A 1929 advertisement in *Canadian Motorist*, for example, portrayed a chic, modern woman standing beside the newest Hupmobile. "Sports ensemble by Regny. . . . Car by Hupmobile," ran the ad. An Essex Super Six sought to convince prospective buyers that they were conforming to popular taste, referring to "this country and world-wide conviction" about the quality of the car. Yet another ad — this one from an American publication — reassured potential buyers that to consider the 1921 Liberty put them among those "whose taste and means incline them to better things."[127] Such imagery was part of the new advertising culture that had developed in the years since the turn of the century. Indeed, the car and modern advertising grew up together, each reinforcing the other's hold over the public. The concept of being smart and elegant was used to sell everything from furniture to cigarettes. There were also aspects of the car that, though played upon by advertisers, were closer to the real mystique of the vehicle.

Central was the idea of independence. This was your personal vehicle that could take you where you wanted when you wanted. In dozens of advertisements and articles the theme of independence was promoted in myriad ways. To a surprising degree, women were depicted as the driver of the automobile. The message conveyed by those ads seemed to emphasize several things, all related to independence. The ads implied that it was easy to operate the car and that the modern woman need not fear this new technology. Any woman could do it. This was no small matter to a generation of women who, born and raised in cities, had increasingly less knowledge and skill in horsemanship. It was also a message not lost on the urban man who, though less willing to admit such things, was himself less skilled with the horse than his forefathers had been. "It's a man's car but it's a woman's car in the sense that it's so easy to operate," said an Overland ad in the early 1920s.[128] The image of the woman driver also linked the car to the modernity of the 1920s. The old Victorian days were gone. A woman who had access to a car wasn't dependent on some man but was free to go about her business. So efficient was the car, moreover, that family duties need not be forsaken in doing so. There was adventure to be had out there beyond the world of the family and the confines of the home. The car provided the means to discover it.[129]

The advertisements emphasizing independence were so powerful because they reflected a genuine public view of the car. Articles on motoring in the early years focussed less on mechanical attributes and speed than today's magazines and more on the romance and adventure of touring. The car was a vehicle that freed the individual from the fixed lines of the railroad and opened up whole new areas of countryside. Driving was still sufficiently new and the countryside sufficiently uncluttered by other cars that there was a real sense of adventure to motoring beyond the city. People, in the words of one article, became "Knights of the Road" heading out to to see what could be seen. Trips to the end of the road in Cape Breton or into the Rocky mountains were portrayed in 1929 in terms that are associated more with modern backpacking than with motoring in the 1990s.[130] The car was flexibility, independence and adventure rolled into one. A 1929 advertisement entitled "Beyond the Barriers of Everyday" caught the mood perfectly. The picture was of a family having a picnic in a wild, wind-swept setting reminiscent of a Group of Seven location. The father stands in the centre of the picture as if guarding the situation while a very lavish picnic is spread about. "Break down the barriers of everyday," the ad read. "There's happiness ahead. . . . The outstanding Chevrolet is the magic carpet that lifts us far beyond the barriers of everyday life. The joys that lie round the turn of the road or over the hill. . . . You too, can seek and find them in your Chevrolet."[131]

The growth and development of Canadian roads must be set against the popularity of the automobile. Cars need roads, and it more or less followed from this that car enthusiasts were road enthusiasts. As the car became a part of Canadian culture the demand for roads grew. The translation of this demand into policy during the first generation of car ownership was extremely important. For by the late 1920s the whole complex set of lobby groups, policies and taxes that shaped roads in this country was in place. So too, to a surprising degree, was the modern Canadian road system, at least in embryonic form.

Support for improved roads predated the car. By the late 19th century both urban bicyclists (a new craze) and rural agriculturists were dissatisfied with the state of Canadian roads. Moreover, this was an age of reform — interlocked groups of social reformers were advocating everything from temperance to better sewers. Amidst the reformism there was, as well, social insecurity.[132] Farmers in central Canada in particular were nervous about the future as an increasing number of their children headed into the cities. Industry seemed poised to replace farming as the most important economic sector in Canada. Rural Canadians were an important force, however, constituting some 70 percent of all Canadians in 1891. They were determined to preserve their position in the community. New parties sprang into existence. Various campaigns sought to bring the benefits of the city to the countryside, hoping thereby to remove the temptation of the city. Over the next few years rural telephone systems and rural electrification would become major issues. Improved roads fit nicely into this program. Improvements would presumably reduce transportation costs and thus improve the farmer's standard of living. They would also reduce the isolation of the farm family and, it was hoped, lessen the attraction of the city.

Still, compared with the massive support of such movements as temperance, a small meeting at the Canadian Institute in Toronto on February 9, 1894 did not seem very significant. Indeed, Andrew Pattullo of Oxford County opened the meeting with the comment that "the attendance will not be very large this morning," and he apologized for the absence of any important political figures. It was in this unlikely atmosphere that the Ontario Good

Roads Association was formed, and the date is as good as any to mark the turn-around of the Canadian road system.[133] For despite Pattullo's deprecatory comments, the good roads movement in Ontario received a significant amount of attention. Cabinet ministers and senior government officials regularly attended. Before long good roads associations sprang up in other provinces. By 1914 F. H. Dandurand of Montreal had successfully formed a Canadian Good Roads Association. In 1917 it was chartered by the Dominion Parliament.[134]

The good roads movement was begun by farmers. Initially, farm associations and ministers of Agriculture showed the greatest interest in it. It was the rise of the car culture, however, that turned the good roads movement into a national cause. Moreover, the movement, though very much the outgrowth of the era's reformism, was unique in the way it blended politics and science. The annual meetings were combinations of technical discussions of road building, discussions of motoring activities and political rallies designed to impress government and public both with the need for better roads. The associations also became significant political forces. From the beginning they attracted the attention of provincial governments. In 1915 (the first year the national proceedings were published) a combined Dominion-Ontario meeting in Toronto showed that the elite members of society had recognized the importance of good roads. The Mayor, the President of the University of Toronto, provincial civil servants and government ministers all attended. It was thus no exaggeration when the Ontario Minister of Public Works concluded that "You have laid the foundation by creating a public opinion" on the matter of roads and that as a result the principles are no longer debated. It is a question of "devising ways and means to meet the different situations."[135]

In 1915 the car was not yet a mass phenomenon. After World War I the car culture took hold, and so too did the Canadian Good Roads Association (CGRA). In 1920 the CGRA held its annual meeting in Winnipeg, the first one held outside of central Canada. Through the 1920s newspapers carried extensive coverage, and the old central Canadian organization was increasingly a national one. In 1925 the Governor General, Lord Byng, attended its annual banquet, and national as well as provincial figures clamoured to be associated with the organization. The attraction of the movement reflected both the public mood and the prestige of a lobby association that was dedicated to the scientific improvement of the Canadian road system.[136]

Paralleling the good roads movement were the provincially based motor associations that would eventually evolve into the Canadian Motor League. A U.S.-inspired network of non-elite associations of local automobile clubs dedicated to the promotion and assistance of "automobility" soon took root. The development of these associations varied considerably from province to province. By World War I the Ontario Motor League was a well-established body with connections to both the Ontario Good Roads Movement and the government. In other provinces a provincial body was still well in the future. It was 1926, for example, before the Alberta Automobile Association came into being as a result of the merger of local clubs.[137]

Like the good roads associations, the motor associations became lobby groups. As early as 1915 the Ontario Motor League was instrumental in arranging a reciprocal licence agreement between Ontario and New York State. Previously drivers had to buy a New York licence plate before they could cross the border.[138] Interprovincial and international reciprocity soon became the norm, thus extending the horizons of the car driver and the potential of the tourist industry. Other campaigns followed, including one to get all Canadian provinces to have motorists drive on the right. As the automobile numbers increased the motor associations also campaigned for more traffic safety. The motor associations also collaborated with and supported the good roads associations that had grown up in various provinces.[139]

There were differences in the evolution of the two types of associations, however. The good roads associations quickly developed a technical interest, and the problems of road construction as much as government policy became their focus. Also, the various provincial good roads associations were, by the 1920s, overshadowed by the national body. In contrast the automobile associations had always had a "facilitation" role. They were the clubs of the drivers, and therefore travel guides, insurance schemes, international driving permits and club associations dominated their non-lobbying interests.[140] They were, overall, definitely non-technical in orientation. Also, in contrast to the good roads movement, the motor associations remained provincially based. Though the Canadian Automobile Association (CAA) was formed in 1915, it was merely a paper organization until 1957. Even today the CAA is small compared with the huge provincial counterparts that underpin it.

Several forces thus came together to shape road policy in the first 30 years of the 20th century. The primal force was the new technology of the car. Both as a form of practical transportation and as a cult of adventure and freedom, it created a totally unprecedented demand for good roads. Already in place as that demand grew, however, were a series of provincial organizations and then a national one dedicated to the improvement of roads, connected to the engineering and political elites of the day and seemingly well received by press and public. Then, parallel with the growth of the car came the car club, lobbying in the name of the driver and linked to the good roads associations, sometimes formally yet always informally.

These developments meant that government neglect of roads soon changed. Even before the car really took hold, the good roads movement and the demands of modern industrial society began to affect policy. In Quebec the provincial government moved through the Department of Agriculture in 1897 to give subsidies to municipalities for road improvement. In New Brunswick where intermunicipal roads were under direct provincial control, planning and funding improved. In Ontario a "Provincial Instructor in Road Making" was appointed in 1896, but the most important step came in 1901 when the *Highway Improvement Act* was passed. This provided a subsidy from the province to county road operations and marked the beginning of a long-term trend toward centralization in road construction. In Quebec, Acts in 1907, 1911 and 1912 regularized the principle of a provincial presence in both the funding and construction of roads.[141]

Centralization was necessary, for the car made the jurisdictional boundaries of the 19th century obsolete. When roads were relatively marginal feeder systems, it was enough for local units to take responsibility for them and to use the inefficient statute labour system to maintain them. Once the car arrived this had to change. For one thing, the longer distances now travelled on land meant that the burden on roads in an area might come from residents miles away. For another, the growing importance of the road system demanded some consistency of funding and construction. As early as World War I, for example, the City of Toronto realized that there was little point in improving its own roads if, once the traveller hit the city limits, travel ground to a halt. It therefore convinced the Ontario government to create the York Highways Commission to develop and maintain roads for 15 miles (24 km) around the city.[142]

The inappropriateness of local government being responsible for road policy after the advent of the car was recognized across the country. The next decades saw a trend toward centralization of road responsibilities. By World

War I most provinces had a distinct roads department or a division within departments of public works. The previously purely local system was complicated by a series of statutes and policies that provided subsidies to local units of government and saw the provinces directly involved in road construction. There was even federal involvement. In 1911 Robert Borden's Conservatives came to power. Borden pledged to take a more active role in facing modern problems than had his laissez-faire predecessor, Wilfrid Laurier. One of the first steps the Government took was to introduce a bill to provide federal funds to assist in the development of a national trans-Canada highway. The bill was defeated by a hostile Senate, but at the end of World War I the Government reintroduced it in slightly different form and passed it as the *Canada Highways Act.*[143] The involvement of the federal government, along with the growing role of the provinces, indicates just how far roads had come from being a purely local matter.

The emerging programs of road subsidy and construction at the provincial level were extremely expensive. Fortunately, the car, which was what created the burden, also provided the solution. Taking their precedent from the United States, the provinces began to impose taxes on cars to cover the costs involved in supporting them. Motor vehicle licensing provided an early source of revenue. Ontario began the practice in 1903, registering all of 220 vehicles that year.[144] Before World War I the registration or licence fee was also adopted by other provinces.

By far the most lucrative source of revenue, however, was inspired by a number of Western states shortly after the war. Beginning in 1919 Oregon, New Mexico and Colorado taxed fuel to raise money specifically for road construction. By 1925 the tax had proven so lucrative that some 44 states had adopted it.[145] Not surprisingly, the provinces were quick to notice the tax. They were facing unprecedented costs as the demands for roads grew. The *Canada Highways Act* only made the pressure greater: it had provisions for Government funding on a cost-sharing basis. If the provinces were going to take full advantage of this federal largesse, they were also going to have to pour large amounts of money into the road system. The fuel tax had the dual attraction of being lucrative and focussed on the very group that would most benefit from the new roads — the car user. In 1922, Alberta was the first province to implement a fuel tax. By the late 1920s every province had one.[146]

Initially the fuel taxes were modest and seen as a supplement to licence fees. It did not take governments long to discover that a hidden user-tax like this was more lucrative and elastic than increases in licence or similar fees. As a hidden tax and as one that varied depending on the use of the vehicle, it also seems to have been more accepted. There was some outcry in Ontario when the first fuel tax was increased in 1925, but generally the motoring public seems to have been relatively willing to accept the burden.[147] By the end of the 1920s a series of tax increases and the growing number of cars on the road meant that fuel taxes surpassed licence fees (see Figure 8). Within a few years fuel taxes accounted for approximately three quarters of all user-impost revenue.[148]

By the mid-1920s then, some important principles had been established for road policy. Most importantly, the new cost of roads had been met to a large degree by new taxes on road users. Over time the exact percentages of user-taxes devoted to highways would vary. In the 1920s, though figures

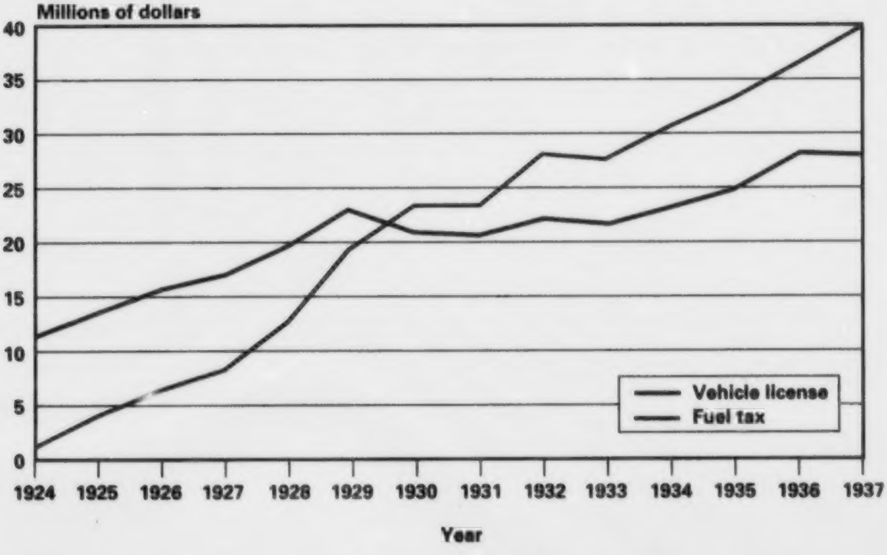
COMPARATIVE PROVINCIAL REVENUE FROM FUEL TAXES AND LICENSING FEES



Source: Statistics Canada (formerly Dominion Bureau of Statistics), *Canada Year Book*, 1925–1945.

are imprecise, it appears that road costs outstripped taxes. In contrast, during the Great Depression the cash-starved provincial governments spent less on roads than they took in. Then, after World War II, the percentages dropped again as massive road-building efforts were undertaken. In general, however, a rough correlation was maintained over the long term between user-tax revenue and expenditures. Occasionally this tie was required by legislation, but even where it was not the correlation existed as a matter of policy. Various commissions and investigations during the interwar years restated the principle that user-taxes on motorists should provide the basic tax support for the highway system.[149]

Two other precedents were set in the 1920s. First, the roads were to be public property. This may seem obvious, but remember that railroads were not public property (except when bankruptcy left no choice) and there had been considerable use of toll roads in the 19th century. By the 1920s, however, toll roads had fallen out of favour and were gradually assumed by the appropriate government. In Ontario, for example, the last toll road was made free in 1926. It would be another generation before toll roads reappeared.

Second, though roads were clearly a provincial matter, the federal government had recognized the overwhelming importance of the system and become involved. The 1919 Act, originally intended to expire in 1924, was in fact extended to 1928. The Act set aside $20 million of federal government money for cost sharing with the provinces. Each province would have access to $80,000 automatically. The rest was to be divided up in proportion to population. To qualify for the money the provinces had to be meet standards of construction established by the federal government. These were not high by modern standards but do indicate the roadway system was being designed for cars rather than foot or horse traffic. The federal government also had a say over which roads were eligible, though any main road seems to have been accepted. In this age of criticism of anti-patronage sentiment, all contracts had to be let by tender. When these conditions were met the cost-sharing system would come into effect: the federal government would pay 40 percent; the provincial government, 60 percent.[150] The federal assistance does seem to have been important in the great construction effort of the 1920s. The provinces were provided with welcome financial assistance at a time when there was tremendous demand for new roads. The federal involvement also set a precedent. Thereafter provinces continually sought greater federal involvement in the highway system. The federal government's involvement, however, has been intermittent: the Government oscillates between a desire to create a truly national highway system and a reluctance to get involved in a very expensive area outside its own jurisdiction.

The basis of the modern road system was established in the 1920s. In 1918 most of the system was still primitive. The only significant stretch of paved highway outside the cities was the concrete highway between Toronto and Hamilton. Only in parts of southern Ontario and in the area surrounding Montreal could one talk of a road system suitable for cars. Even then the roads were seasonal, closing down whenever the snow got too deep. In Nova Scotia, where the roads were better than in many provinces, the system was still sufficiently fragile that there was a provincial law on the books prohibiting motor traffic during the spring thaw.[151] The side of the road the motorist should drive on varied from province to province, and British Columbia had only just asserted uniformity on that *within* the province.[152]

The 1920s revolutionized Canadian highways in several ways. First, the technical obstacles to the development of a modern highway system were overcome. Roads designed for the horse and wagon were not suitable for the car. The speed and design of the car created new demands for gentle curves, limited grades and smooth surfaces. As well the wear and tear of cars were such that even a well-designed carriage road was unsuitable for car traffic. As the President of the Ontario Good Roads Association put it in 1914, "the automobile itself is quite a harmless instrument — a broad soft tire, but the rapidity at which it is driven upon our roads makes it a regular road smasher."[153] In the first 20 years of the century, failure to understand the implications of this fact led to numerous errors of planning. "Waterbound macadam," for example, reacted very differently under horses and cars. The slow, steel-rimmed wagon wheels compacted the macadam surface. The fast, rubber-tired car carved deep ruts into it.[154] In all areas, from drainage to gravel coverage to safe curvature, the car road had requirements considerably different from those of the older wagon road.

Second, until well into the 1920s only Ontario really had the demand or resources to create a full-fledged system of highway construction and maintenance. Other operations appear to have been relatively haphazard. In Alberta, for example, only one quarter of the maintenance appropriation was spent in 1922. Partly as a result of this, the legislature slashed the budget for 1923, leaving Public Works without the funds to do any but "the most urgent work."[155] That same year the entire maintenance cost for the main Edmonton–Calgary highway was only $6,961. The same general records of small expenditures, ad hoc arrangements and lack of long-term policy appear as well in the records of other provinces, or at least such other provinces as bothered to print annual reports on highway activities at all.

This changed dramatically through the decade. A 1923 report by the Ontario Minister of Highways said, "A much greater expenditure is to-day necessary and justifiable, as compared with the days when roads carried horse-drawn traffic alone."[156] Certainly roads received a great deal more attention than they ever had before. With aid from the Dominion government, provincial highway budgets multiplied many times through the decade and became one of the major expenditures. Highway departments expanded and became much more involved in long-term development strategies rather than merely keeping existing roads passable. In British Columbia, for example, work began on the tremendously expensive trans-provincial highway, which, when finished would create "a serviceable highway from the Coast to the Crowsnest Pass."[157] In Alberta the *Canada Highway Act* encouraged the province to create a high-quality north-south highway. By the end of the decade maintenance expenditures on it were 25 times higher than they had been in 1923.[158] In Ontario the emphasis was on the development of the King's Highway system, including a considerable amount of hard surfacing. New Brunswick was starting from somewhat farther behind than Ontario, but it too put considerable funds into developing a main trunk system and improving rural roads.

The final change came in the response to weather. Until the 1920s roads were at the mercy of nature. Snow-removal equipment was primitive and the expenditure small. Ontario, for example, spent less than $5,000 a year on snow removal through the early 1920s. Quebec spent less. The result was that roads, as always in the past, were in effect seasonal operations outside of the cities. Improved surfaces and drainage lengthened the season, but a snowstorm still shut the system down. Cars disappeared and sleighs took over. The roads "returned" to the 19th century.

As cars, buses and commercial vehicles became a standard part of the national culture and economy, however, such seasonality inflicted an ever greater social and economic cost. By the later 1920s all provinces were making more of efforts to create an all-weather road system. Ontario bragged that it maintained some 1,200 miles (1,900 km) of roads all winter (though snow could and did shut them for days at a time). Other provinces had neither the hard-surface mileage of Ontario nor the same money to spend on snow-removal equipment. Nevertheless, all provinces sought to keep at least the main highways open through the winter.[159] It would be another generation, however, before year-round car travel became the norm outside the cities of Canada.

What did this all mean by the end of the decade? What was the state of the Canadian highway system at the onset of the Great Depression (and it wouldn't change much for the next few years)? How, if at all, were railways affected by the rising popularity of the car? The most striking thing is the change that had taken place in a decade. There were still a good many bad roads, but the Canadian highway system had been redesigned and rebuilt for the car. Tracks had been turned into regularly passable roadways. Links between cities had been upgraded so that intercity automobile travel was routine, at least over short and medium distances. Nor was the car an exotic sight any more. Summer traffic on the Toronto–Hamilton road was upwards of 5,000 cars a day by 1926, and by the end of the decade the main road out of Vancouver was carrying more than 9,000 cars a day.[160]

In contrast to the spread of the car, the use of the horse was declining. At the end of World War I roads everywhere had to carry both horse-drawn and motorized traffic. By the end of the decade the horse and carriage had become an increasingly rare sight along major highways, especially in the more urbanized east. Not only were there fewer of them, but as car numbers and rates of speed increased it took a degree of hardiness to bring a horse onto the main highways. Horses and carriages were now more or less confined to rural areas, and even there they tended to stay off the main roads.

Related to the motorization of the roadway was the development of commercial bus service. Through the 1920s bus service improved. In 1926 regular coach service began between Calgary and Banff. By the end of the decade the main cities of Alberta were served by scheduled bus lines.[161] In Ontario, as Figure 9 indicates, an extensive system of bus routes had been developed, providing the first significant competitor to railways for the public passenger dollar. Railways, indeed, had now cast aside their earlier friendly attitude toward the car and were increasingly demanding that buses "pay their fair share." Complex studies and adjustments of licence fees, gasoline taxes and related issues would become a major subject of discussion through the depression years as all modes of commercial carrier found their revenues in decline.[162]

Figure 9

For all the improvements that had been made in the road system, two facts that emphasize the limitations that still existed stand out. First, driving in the 1920s meant driving for the most part on gravel or unpaved roads. In Alberta, for example, the bulk of federal funds under the *Canada Highway Act* had gone to improve the main north-south route, Highway 2. By the end of the decade the province could boast of a "modern" gravel highway extending from Lethbridge to Edmonton. North of that it was still a rudimentary dirt road. A small section (70 miles [113 km]) was even paved in the early 1930s, but the Great Depression meant that most of it was gravel until after World War II.[163] The same conditions prevailed in Manitoba and Saskatchewan and through much of the Maritimes.

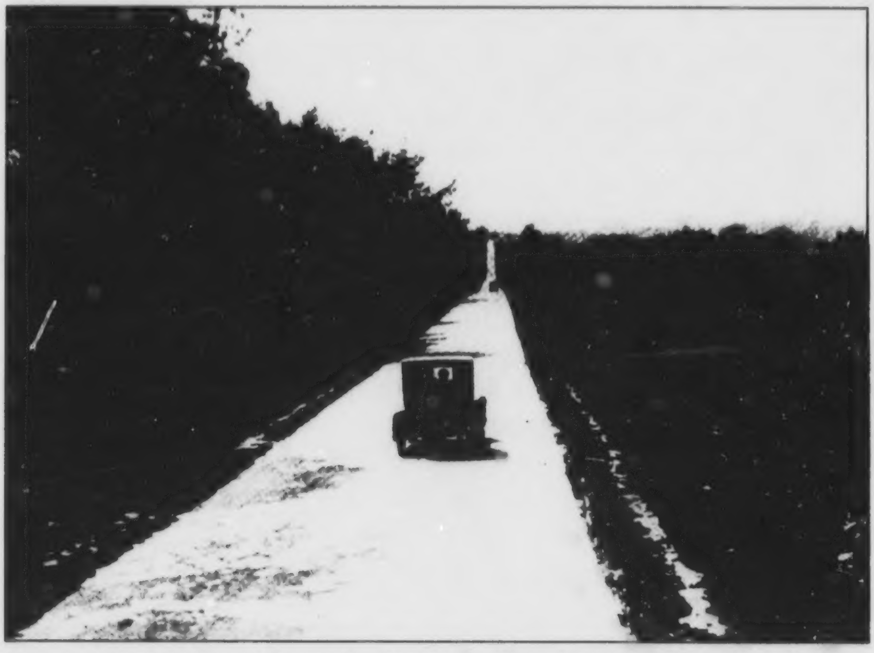
There were exceptions to this rule in the vicinity of the major urban centres. British Columbia's roads on the lower mainland and southern Vancouver Island had hard surface by the later 1920s. So too did Quebec's highways in the vicinity of Montreal. Ontario had by far the most extensive system, with some 1,800 miles (2,890 km) hard surfaced in one fashion or another as early as the mid-twenties.[164] The main highways westward and eastward from Toronto were paved, and it was possible to go all the way to Montreal or Windsor on a paved highway. Even in Ontario, though, pavement was restricted to the major arteries. If one deviated from what is now known as the corridor, gravel became the rule. Only about 5 percent of Ontario highways were hard surfaced by the end of the decade. Moreover, even the paved highways were relatively narrow, with 18-foot (5 m) surfaces and gravel shoulders (see Figure 10).

At the end of the 1920s Canada's highway system was also limited by its regional nature. The *Canada Highway Act* had not tied grants to any sort of trans-provincial linkages, and provincial governments followed traffic demand rather than encouraging interprovincial links. At the end of the decade it was still impossible to drive across Canada. British Columbia was not connected to Alberta despite the efforts to create a trans-provincial highway. Ontario was not connected to itself: there was no road around the north of Lake Superior. Given the accessible American road system, the problem was probably more symbolic than real. More difficult and more costly was simply the patchiness of the Canadian road system. Except perhaps in the Windsor–Montreal corridor, long-distance travel by car was still difficult. Speed limits were still relatively low (they varied, but 30–35 mph (48–56 km/h) outside cities was typical). "Good roads" were still confined to the major transportation corridors and oriented on provincial rather than national needs. Whereas the railroad system had strong nationalist associations, the road system was, after the first 30 years of the car, regional in orientation and uneven in standards.

The car was sufficiently important by the 1920s, though, that the railways began to complain about "unfair competition." "Motor vehicle competition by private automobile, bus and motor truck," complained the CNR in 1931, "has made serious inroads into the railway's traffic. . . . The use of the motor vehicle beyond its proper economic sphere can have no other effect than to increase the total cost of transportation to the citizens of Canada."[165] That "proper sphere," apparently, did not include competition with railways. Concern focussed on two areas in the interwar years. The first, not relevant to this paper, was short-haul freight: commercial trucking firms entered into competition with railways quite early and quite effectively. The second is relevant, however: the railways saw the car and bus as just as much a threat to passengers as to freight.

*Figure 10*

**No. 2 Provincial Highway, 5 Miles East of Bowmanville**



**Source: Ontario Archives, Negative No. A0913 (reproduced in Ontario, *Annual Report of the Department of Public Highways*, 1926, Frontispiece.)**

The main concern was the attractiveness of the car to the individual or family going a relatively short distance. A trip from, say, Hamilton to Toronto or Brandon to Winnipeg by horse and wagon was not competitive with the speed, comfort and even cost of the train. The same could not be said when it came to a comparison between the train and the car. Even more threatened was the very short haul. Why travel according to someone else's schedule over a distance of 10 or 15 miles when you could simply start the car and drive off?

An historian of the Canadian national system confirmed the concerns of railways, noting that the "motor car had taken a heavy toll of railway passenger traffic."[166] The statistical material available also shows some support for the railways' fears. Though the 1920s were generally good ones for the railways, several indicators imply either a static or somewhat declining passenger market. As Figure 11 indicates, for example, there was a slow decline in the number of railway passengers through the decade despite improving economic conditions after 1921 and a growing population. Figure 12 also gives at least indirect evidence that there was a correlation between the rise in cars and the erosion of passenger numbers on the railways.

The competition from cars and buses at any time between the wars should not be overstated, however. For one thing there was simply not enough of them. As mentioned, even by 1929 there was only one car for every nine Canadians. For the great majority of Canadians, public transportation was still the standard means of travel. Even for those who had cars, the technology and infrastructure of motoring were not yet adequate for regular travel over anything but the shortest distances. Cars had come a long way in the decade, but they were still designed for relatively low speeds and short distances. Suspension systems were rudimentary. Most cars were not heated. For that reason as well as the primitive nature of snow clearance, much motoring was a seasonal phenomenon.

Between the wars the most serious challenge to the railway came in a specific area, short-haul commuter traffic. It was the electric and street railway, designed for brief trips and constructed in and around those urban areas where roadways were usually best, that faced the brunt of the competition. Electric railway mileage peaked in the late 1920s, and thereafter abandonment rather than construction was the trend. By the 1950s many cities had totally abandoned their electric rail systems. Others had only a vestige of this once crucial urban and commuter link.[167] Across greater distances, however, the car was but a minor threat to the dominance of the railways in passenger travel. The commercial airplane was such an insignificant factor before World War II that all discussion of it is best deferred until after 1945.

## THE GREAT DEPRESSION

In 1929 the economy turned downward as world commodity prices collapsed. Canada, as a major exporter of such commodities, was quickly affected. The Prairies had a bad year in 1929, and by 1930 the economy was in trouble across the country. For the next three years the Canadian and world economies would continue to shrink until, at the bottom, world trade was at only one third of the level of 1929. Then, for the rest of the 1930s, there was only slow and intermittent improvement. Not until the World War II was the Canadian economy prosperous once again. In the intervening years all aspects of Canadian passenger transportation were affected.

The Great Depression rapidly brought the highway boom of the 1920s to a halt. This is hardly surprising. The depression shrank the financial resources available to governments. In 1930 provincial revenues had reached an all-time high of $188 million. By 1933, the low point of the depression, they had dropped to $152 million, or by almost 20 percent.[168] At the same time provinces were being pulled by bankrupt cities into more and more involvement in relief programs. As a result deficits rose and so too did the pressure to cut costs wherever possible. Road programs were a natural target. For one thing, government cutbacks are often carried out at the expense of the infrastructure. Capital projects can readily be delayed. So too can maintenance, which can be minimized with the recognition that a delay of a year or two will unlikely do much harm.

Another factor reinforced the tendency to delay capital construction. With the depression, automobile ownership ceased to increase at anything like the rate it had before. Indeed, for a period between 1931 and 1934 absolute automobile ownership decreased in Canada (see Figure 13). This would happen again, though at a lesser rate, between 1941 and 1945 as wartime restrictions curtailed production. Even when registrations did turn upward in the later 1930s the rate of growth was much slower than in the 1920s (see Figure 14).

At a time when governments were starved for revenue this decrease in the rate of growth of cars for some 15 years (and absolute drop in ownership for part of the time) provided a welcome respite. Capital expenditures could be slashed not just on the basis of fiscal necessity but because of decrease in demand. Maintenance was in theory less affected by the halt in the growth in the number of cars, but that too was cut back severely. Revenue decreases, said the 1932 *Alberta Annual Report of the Department of Public Works,* "made it imperative to curtail highway expenditure to such an extent that the utmost economy and watchfulness became necessary." The *Ontario Highways Report* for 1933 referred to a decrease in activity both in maintenance and construction because of "the depressed state of the financial economy."[169] It was the same everywhere as provinces finished off old projects and postponed or cancelled new ones.

*Figure 13*
**REGISTERED MOTOR VEHICLES**

The overall decrease in provincial expenditure on roads was dramatic, declining by 60 percent between 1930 and 1933. Thereafter expenditures increased, but it was 1937 before highway expenditures recovered to previous levels. In the meantime user taxes on cars actually increased: cash-starved governments raised the vehicle registration fees and fuel taxes repeatedly through the decade. At the end of the 1920s user fees had recovered only about 50–60 percent of the total provincial highway expenditure in Canada. In five of the 10 years of the Great Depression user revenue matched or exceeded total provincial highway expenditure. User taxes were now subsidizing general revenue rather than vice versa. This pattern would become even more dramatic in World War II as road taxes outstripped expenditures during every year of the war, sometimes by as much as 50 percent.

Hard as the roads were hit, the railways were hit harder. The depression affected them almost immediately. Revenues dropped in 1929 and again in 1930 as wheat shipments declined from the Prairies. Then, as the depression hit home, people travelled less on business or pleasure, and passenger

*Figure 14*

traffic plummeted. The joint operating revenue of the two systems decreased from $469 million to a low point of $262 million, a decline of 45 percent. In response, both railway systems scrambled to avoid collapse. They reduced their operations, drastically slashing the number of trains, maintenance levels and the work force. By the low point, activities had been cut to the point that it was as if one of the railway systems had disappeared.

The two railways were affected differently. CPR was better able to weather the storm, though it had to suspend dividend payments for the first time since the completion of the transcontinental line and even had to turn to the government for some short-term debt guarantees.[170] Things were worse for CNR. The fixed debt CNR had inherited from the Grand Trunk and Northern railway systems meant that even in good years it was difficult for it to meet expenses and debt charges. To make matters worse, CNR was not really a coherent network of railways. It was a patchwork, put together from all those overextended, non-viable lines the government had assumed over the years. Finally, CNR had been as aggressive as CPR in adding to Prairie branch lines through the 1920s, which of course added to the debt as well.[171] At the beginning of the Great Depression CNR's debt was massive, equivalent to one quarter of the national debt.

CNR's financial position made it especially vulnerable to the depression. In 1929 CNR had an operating revenue of nearly $260 million, against operating expenses of just under $215 million; the profit therefore was approximately $45 million, excluding payments on debt. By 1933 revenue had declined to less than $150 million; operating expenses, to $143 million. The ongoing operation was just a little more than half the size it had been before the Great Depression.[172] In the same period, the number of employees declined from more than 111,000 to 70,000.

Passenger systems played an important part in both the decline in revenue and the reduced services. During the 1920s, as we have already seen, passenger- related services like hotels had been major expenses for both systems. A 1931 royal commission used the benefit of hindsight to condemn the two railways for creating "a standard of passenger travel quite beyond the needs of the country" and for excessive expenditures on hotels.[173] Then, after all that expenditure, passenger travel collapsed. As Figure 15 indicates, the decline in ridership continued until 1933, by which time the railways were carrying half the passengers they had in 1928. Thereafter the decline halted, and there was even some improvement. Even after a decade, however, passenger traffic had improved only marginally from its low point and was far below the level of the 1920s.

Passenger revenue declined even more sharply than passenger numbers. As Table 2 shows, between 1929 and 1930 CNR experienced a 14 percent drop in passenger revenue, with another 29 percent drop in 1931. People simply could not afford to travel any more. Sir Henry Thornton, President of the company, had always been interested in passenger service. Nevertheless, the company was desperate and immediately moved to slash expenses. New car orders were delayed. Some of the more expensive luxury services (for example, parlour cars, sleeping cars) were cancelled on various runs, and services themselves were slashed. The number of passenger-miles decreased by 480,000 in 1930, more than 3 million in 1931 and close to 5 million in 1932. The CNR *Annual Report* commented that this was "equivalent to wiping out practically one-third of the passenger train service operated in 1929."[174]

Some writers have looked back on the Great Depression as a fundamental turning point in the history of passenger transportation on railways. Until then, this argument goes, the railways had seen passenger transportation (and ancillary services) as an important part of their revenue and as a matter of prestige as well. Then, with the depression, the whole emphasis on passenger service shifted from growth to retrenchment and from prestige to liability. Rail passenger service never recovered thereafter.

There is some evidence for this. There is no doubt that the Great Depression brought a tremendous reduction in service. A good many marginal routes were cancelled; services on others were cut back. The public, which had become accustomed to ever-improving regularity and proximity of passenger services, now experienced the reverse. Even as the Great Depression lifted and some services were restored, rail transportation was not as it had been before. Many of the routes were not revived, and on more major runs there were fewer trains scheduled than before. Even well into the boom times of the World War II, for example, passenger-miles were well below what they had been in the 1920s. As we have seen, both railways trimmed operating expenses by reducing capital expenditures and deferring indefinitely much-needed maintenance on tracks and equipment. Trains became a little more infrequent, services a little more difficult to get at and the level of comfort a little lower. As we will see, the war provided the railway with certain advantages, and a sharp increase in ridership resulted. The conditions during the war were abnormal, however, and once it ended the railways found themselves facing more competition than ever. The decade of the Great Depression and the reduction in equipment and service did much to undermine the railways' ability to meet that competition.

Another reason to think of the 1930s as a turning point comes when one looks at the relative importance of passenger traffic on the system. For it was in the 1930s that passenger traffic on both major lines began to slip in importance. As Table 2 shows, CNR's passenger traffic accounted for 12.32% of revenue in 1929 and only 8.74% a decade later. The same relative decline occurred on the CPR: 6.7% in 1929 and only 4.8% a decade later.[175] When these figures are put together with the lesser declines in the relative importance of passenger revenue of the 1920s, the cumulative trend is quite significant. Passenger services were becoming a peripheral part of the railway operations.

Finally, the 1930s were a turning point because of the changes in the relationship between the railways and the Government. Not surprisingly, given the importance of the railways to the national economy and the tremendous burden that CNR placed upon the Dominion treasury,[176] there was a great deal of controversy surrounding the beleaguered railways in this decade. There were parliamentary hearings, the already-mentioned royal commission and some significant alterations in Government regulatory practices. Sir Henry Thornton, the pro-passenger head of CNR, was removed and CNR was placed first under a board of commissioners and then returned to its traditional form of governance. In 1936 the Department of Transport was formed, replacing the old Department of Railways and Canals.

Perhaps the most important change in passenger transportation arose from the growing concern of the Government. It asserted with increasing force its right to intervene in railway business decisions with an eye to the public good. Of course, as we saw earlier, this precedent was well established under the common-carrier rule. Since 1903 the Board of Railway Commissioners had sought to protect passengers' basic health and safety as well as regulate the passenger fare system. Still, at the beginning of the 1930s, railways made the decisions about what trains to run and whether they should be run at all. The Minister of Railways and Canals summed it up in 1933 when queried about cutbacks in passenger service in northern Ontario. "Such matters as running trains are not discussed in any shape or form with the government. That is entirely a question of railway management."[177]

Such attitudes were feasible as long as the overall railway passenger system was healthy and, for the most part, expanding. The Great Depression destroyed any such assumption. Passenger service was decidedly no longer a growth industry. As with railway service generally, the tendency was now toward a reduction rather than improvement in service. The government increasingly feared, however, that in the panic of railways to reduce expenses the welfare of the public would be ignored. In such circumstances the Government felt bound to step in. Thus in 1933 it passed a new statute requiring railways to get the approval of the Board of Railway Commissioners before abandoning lines.[178] This stopped short of Government supervision of specific passenger services, but it was a significant change in the previous assumption that such matters were best left to the companies involved. Over the next few years both CNR and CPR regularly applied for permission to abandon lines and, on average, won the right to do so in about half the cases. Thus the Great Depression set precedents for dealing with a new reality — declining service. The Government extended the precedent of the common carrier by asserting its right to control branch-line abandonment. The railways, for their part, found themselves in the uncomfortable position of being forced to operate unprofitable lines. Though these precedents applied to abandonment, the practices could and would be extended to the provision of specific services within a few years.

The railways did provide a cheap service for a population that could afford little more. CNR boasted in 1934 that standard fares amounted to only 2.25 cents a mile (1.4 cents a kilometre).[179] Along the way, however, the sharp drop in revenues forced CNR to reduce the choice of trains and the level of service. By the end of the 1930s the train was not as accessible or convenient a mode of travel anymore. Also, despite some improvements such as a limited introduction of air-conditioned cars after 1935, passenger equipment was allowed to run down in the 1930s. The war only exacerbated the problem so that by 1945 equipment was increasingly unreliable and shabby. Massive overhauls and purchases would be needed to bring it back to the standards of pre-depression days. Finally, all of this was happening as the relative importance of passenger service was declining. Passenger service, once the most prestigious part of a railway's business, was not yet seen as an undesired burden, but it was increasingly an operation of peripheral importance.

## WORLD WAR II

World War II saved the railways from imminent collapse. The Great Depression came to a rapid end as the nation produced the goods for a modern industrial war machine. On the Prairies wheat harvests recovered along with world wheat prices, and grain shipments on the railways recovered in parallel, first to pre-depression levels and then to new records. The operating revenues of both railways shot up even more dramatically than they had fallen at the beginning of the 1930s, increasing by 67 percent between 1939 and 1941.

Initially, in a trend that continued from the late 1930s, most of this improvement was in freight services. In the case of CNR, for example, 1939 saw freight revenues increase by 14.6 percent, compared with a 1.5 percent decrease for passenger revenue.[180] It was not long, however, before passenger travel also boomed. The number of passengers carried by the railways tripled between 1939 and 1944 (the peak year). Revenue expanded accordingly, reaching all-time highs in both current and constant dollars.[181] By the end of the war some 60 million passengers rode the trains — five trips for every Canadian citizen.

Much of the boom in passenger travel during World War II was a short-term anomaly, for the recovery of passenger service, spectacular though it was, did not represent a return to a more competitive and hence more profitable position for the long term. With the one exception of 1944, passenger traffic did not recover to a point where it could match the ridership of the 1920s. Railways did as well as they did in the war years for very specific reasons. Car transportation was severely restricted by two factors. Canadians had not replaced their cars very quickly during the depression years. For a time registrations had actually decreased, and even toward the end of the 1930s people tended to hang onto the existing vehicle, make one more round of repairs and hope the thing would run another winter rather than go into debt or squander precious savings to buy a new one. By the beginning of World War II, therefore, Canadian cars were rather old overall. Undoubtedly there would have been massive replacement of them in the prosperity of the war years except that production of new cars effectively ceased by 1940 or 1941. No doubt there was tremendous demand for cars, but they were simply not available. Car registrations actually declined during the World War II, as did the number of miles driven.[182]

There were additional restrictions. Gasoline rationing began in 1942, thus limiting the amount of driving owners of cars could do. Even commercial activities were restricted. Intercity bus trips were restricted to no more than 50 miles (80 km).[183] Taxi travel between cities was also effectively prohibited. Airline travel was still in its infancy, and during the war regular flights were practically impossible to get. Thus, for the duration of the war, there was no real commercial competition for the railways over longer distances: this was a time when wartime business, troops coming home on leave, and relatives visiting troops on station created more than enough traffic to make up for the absence of immigrants or tourists. The formal railway rates for passenger services were not increased during the war because the rates, as with much else in Canada, were frozen under Wartime Prices and Trade legislation. Nevertheless, railways were effectively able to increase revenue by dropping the deeply discounted excursion fares that had been used to lure customers during the Great Depression.

The wartime boom in passenger travel, therefore, did not mark a return to the golden pre-depression years. Yet it was important not just because it rescued railway passenger services from insolvency but because it introduced a new generation to train travel. The train took the soldiers off to war, and the train brought them back home. The train took the young bride off to Halifax or Esquimalt or elsewhere to meet her husband on shore leave from the Navy. The train moved the war materials and responded efficiently to the crisis of these years. Once again, the train's role as a part of the sense of national identity was reinforced.

## 5. THE COMPETITIVE ERA AND THE RISE OF THE PASSENGER POLICY ISSUE: 1945–1967

> . . . we find that there is little social justification and less economic, for the permanent provision of railway passenger services as we know them today. The public, by and large, has already indicated its preference for other modes of travel. . . . (MacPherson Commission, 1961)[184]

Until sometime around World War II, passenger transportation in Canada was dominated by the railway companies. The car had made inroads, but these had been limited by the Great Depression and by wartime restrictions on production. In contrast, the post-war era brought the end of dominance by railways as the car achieved hegemony over shorter distances and the airplane over longer ones. As this happened the railway passenger travel networks became extremely costly to maintain. From the later forties onward the companies sought to reduce or eliminate specific services and increasingly looked for internal forms of cross subsidization and then direct Government support. Politicians and the public, who until then had been focussed on freight rates, increasingly turned their attention to the passenger issue.

Many services have disappeared with minimal fuss when outcompeted by newer forms. Lake- and ocean-going passenger ships disappeared, as did most streetcars. Aficionados lamented their passing, and a few editorials complained about the disadvantages of the loss of service. Generally, however, neither Government nor the public expected such transportation systems to remain beyond their competitive life. Passenger railways were and are a different matter, however. The railway was so vital in the recent past of the nation and its mythology so entwined with national history that abandonment could not be considered just another step in the evolution of technology. Further, the well-entrenched doctrine of the common carrier meant that there were numerous precedents for treating the railways as a public commodity. There were also a rising number of precedents for subsidization of railway services in the name of some national or regional goal. Currents of nationalism from the mid-1950s onward complicated the issue. The abandonment of the railway seemed tantamount to weakening Canada. Regional balances came into question as outlying communities and smaller urban centres complained that the destruction of rail service was a betrayal of their place in the nation. All of these debates occurred against ever-mounting passenger rail losses and a more competitive transportation network.

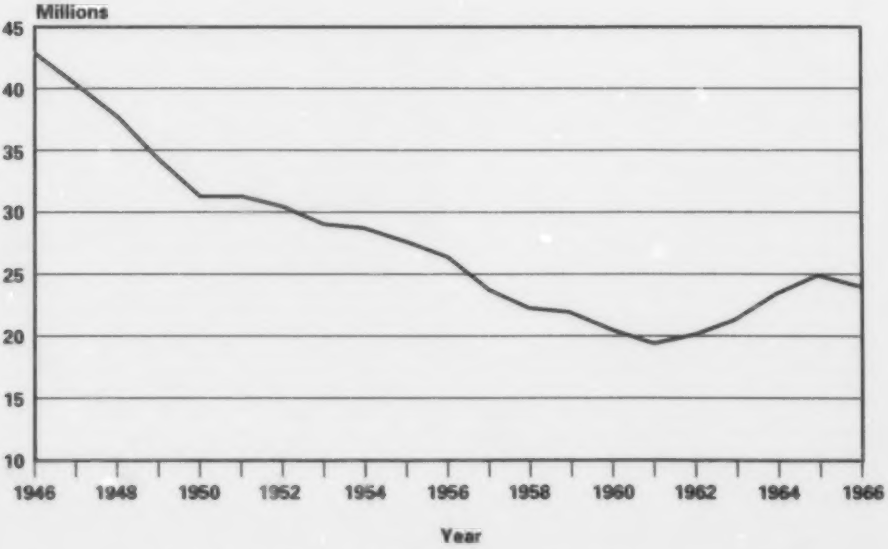
In rough terms the post-war era can be divided into two parts. The first part, from 1945 to the mid 1960s, was one in which passenger transportation and passenger transportation policy was in a state of uncertainty. The government, faced with political pressure on issues like freight rates and line abandonments, did not really look at passenger transportation as a distinct problem. In the meantime travel by car and air was expanding rapidly, changing the economics of passenger rail more quickly than the railways could adjust their policies or practices. The railways were still interested in providing passenger service, but both they and Government seemingly underestimated the changes that would be needed to cope with the new conditions of the post-war situation. The report of the 1961 *Royal Commission on Transportation* (MacPherson Commission) and the passage of the *National Transportation Act* (1967) mark a rather drawn-out transition to the second post-war era. By this time the Government recognized that the previously powerful passenger rail system was less able to compete with other modes. The Government sought to deal with the situation by allowing a combination of abandonment and subsidy, depending on social and economic circumstances. Thereafter passenger rail became a subsidized system in which various policy steps attempted to balance public demands for ongoing rail transport against governmental desires to reduce subsidies and rationalize the system.

Two things link these distinct periods. The Government increased its activity and investigation in the area of transportation in the post-war period. There were two royal commissions on railway problems in just over a decade. In between there was a third (the Gordon Commission),[185] which dealt with the issue as a part of Canada's economy. Freight and passenger rates, which had been more or less stable for a generation, were increased several times, then reduced, and then subsidized as Government sought a solution for the changing situation. Subsidies multiplied in size and diversity.[186] Through all the changes both the Government and the public wrestled with two difficulties. The first problem, as a post-war transportation economist put it, was whether "transportation services to be regarded as business institutions like department stores, factories, or farms, or are they to be looked upon as almost eleemosynary agencies wherein the cost-revenue relationship is subordinate to the welfare of the public?"[187] The second problem was to recognize that a system of regulation that had grown up because of the power and effective monopoly of the railways now had to be readjusted because of their weakness in the face of cars, buses, and airplanes.

## THE RISE OF COMPETITION IN THE POST-WAR ERA

The decline of railway control of land travel after World War II is readily demonstrated. Every measure indicates the same story. After the records set during the war, passenger travel by railway dropped sharply. As Figures 16 and 17 show, the railways quickly found that the ridership levels

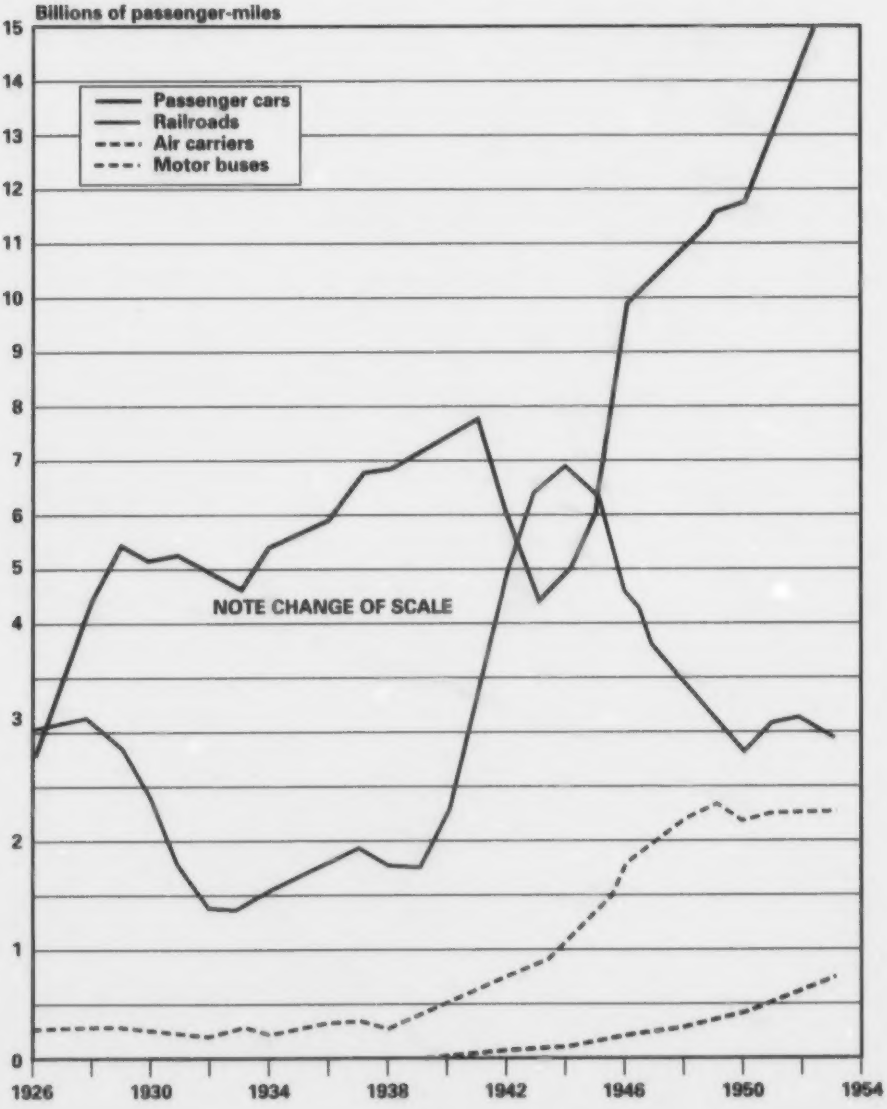
*Figure 16*
*Number of Railway Passengers*



**Source: Statistics Canada (formerly Dominion Bureau of Statistics), *Canada Year Book*.**

Figure 17

ANNUAL VEHICLE-MILES OF TRAVEL IN CANADA, 1926–1953



Source: Gordon Donald Campbell, "An Analysis of Highway Finance and Road User Imposts in Canada," PhD thesis, Purdue University, 1956, p. 62.

of the war years were artificially high. Conversely, car miles increased dramatically once wartime restrictions disappeared. A steady downward trend in both the absolute and relative position of railways began that continued until, by the end of the 1950s, ridership levels were returning to those of the depression era.

Revenue followed numbers. Railways could not increase fares to make up for declining ridership because that would only accelerate the desertion to other modes of transportation. Instead, to keep customers they had to cut fares. Excursion packages, discounts and group rates were used to woo passengers. Some of these helped, but the general trend was irreversible. This is especially striking because revenue was falling, even though Canada's population was rapidly growing as a result of the famous baby boom and high post-war immigration. As Table 3 indicates, the population was using railways much less frequently on a per capita basis. Travelling by train was a much less common experience by the 1960s than it had been even 15 years earlier. The long-term trend was even more dramatic. Average Canadians of the early 1960s took only one fifth as many trips as their grandparents had in the 1920s.

*Table 3*

***ANNUAL RAIL PASSENGER REVENUES AND RIDERSHIP, 1946–1966***

| Year | Passenger revenue (millions of 1971 dollars) | Passenger trips per Canadian |
|---|---|---|
| 1946 | 222.22 | 3.53 |
| 1947 | 178.46 | 3.26 |
| 1948 | 148.31 | 2.99 |
| 1949 | 146.72 | 2.60 |
| 1950 | 131.66 | 2.27 |
| 1951 | 134.85 | 2.21 |
| 1952 | 134.17 | 2.09 |
| 1953 | 128.36 | 1.93 |
| 1954 | 121.81 | 1.86 |
| 1955 | 122.96 | 1.73 |
| 1956 | 124.53 | 1.62 |
| 1957 | 122.91 | 1.38 |
| 1958 | 106.47 | 1.25 |
| 1959 | 100.27 | 1.20 |
| 1960 | 93.14 | 1.09 |
| 1961 | 81.60 | 1.03 |
| 1962 | 79.84 | 1.04 |
| 1963 | 77.07 | 1.09 |
| 1964 | 81.04 | 1.19 |
| 1965 | 81.61 | 1.25 |
| 1966 | 75.21 | 1.16 |

**Source: Statistics Canada, *Historical Statistics of Canada*, second edition, F.H. Leacy (ed.), 1983, Series T44, T62.**

In the 1930s the railways had suffered along with the rest of the economy. This time revenues were declining despite national prosperity. With the exception of only a couple of short-term recessions, Canada underwent steady economic expansion from the war's end until the later 1960s. In the case of railway travel, however, the economic boom only exacerbated the difficulties of passenger transportation, for it enabled the more rapid introduction of alternative forms of technology, the car and the airplane.

## CARS AND ROADS IN THE POST-WAR ERA

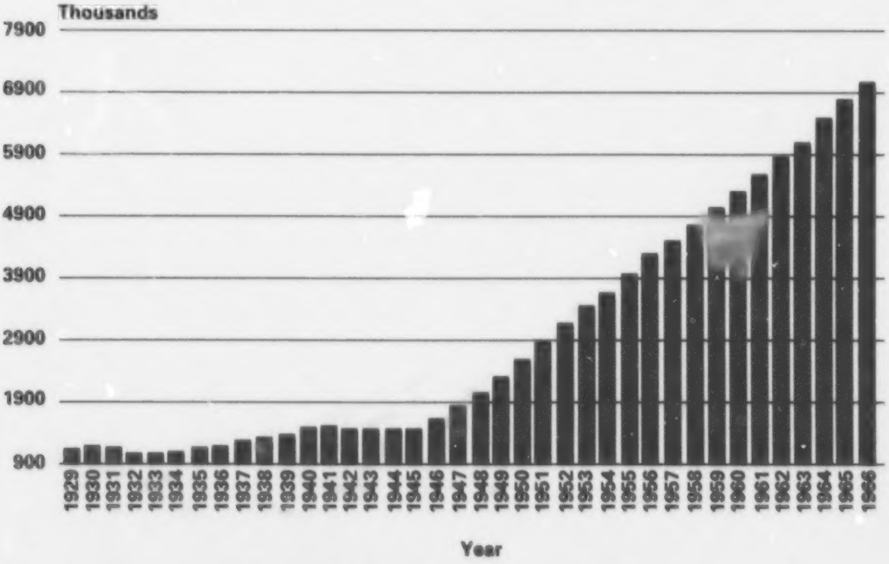
At the end of the war the desire for the car presented a classic case of pent-up demand. The war years had brought full employment, and the nation had quickly climbed out of the depression. Under normal circumstances the aged fleet of cars possessed by Canadians would have been turned in over a period of years. New buyers would have entered the market as economic circumstances warranted. As we have seen, however, car production was halted during the war. It was thus the railway that reaped the benefits of wartime travel. The demand for the car continued to build, however, and in the post-war period the car was no longer a luxury but a necessity.

The only thing that was required to release this pent-up demand was prosperity. That came. The period from 1945 through the later 1960s was one of the most prosperous in Canadian history. The average Canadian's standard of living would double in these years, and one of the things that Canadians saw as an absolutely necessary part of that rising standard was a car. After more than 15 years of practically no growth Canadian car registrations exploded following the war (see Figure 18). In 1946, despite limited production of cars, registrations increased by 74,000; in 1947, by 136,000. By 1952 registrations were double those of 1945. It was estimated that more than 50 percent of Canadian families owned a car by then. "In other words," said one contemporary observer, "it required only seven . . . years to duplicate the motor vehicle production and ownership achievements of the previous 45 years."[188] That was just the beginning. A decade later car registrations had doubled again. In 1945 one in eight Canadians had owned a car. By 1954 it was one in four and by 1965 one in three.

Patterns of ownership also changed. First, class ceased to be a serious barrier to car ownership. By the 1960s all but the very poor owned a car, and other factors, such as age or disability, were more likely to prevent car ownership than income. Second, regional variations in per capita ownership decreased. From the beginning, Ontario had had more cars per capita than any other province. In 1945 that was still the case: Ontario had more than twice as many cars per capita as, for example, Quebec. In contrast, by the mid-sixties the differences between provinces were relatively small.[189] The car had become a mass phenomenon.

Critics have railed against the car of the 1950s. They have pointed out, with some reason, that it was overpowered, ridiculously unsafe and a polluter. Such criticisms did not reflect the popular mood. North Americans felt a tremendous attachment to their cars in the post-war decades, for however far it fell short of the ideal, the 1950's car was a great improvement over what had gone before. It was more powerful, smoother riding, heated and, after the mid-1950s, often equipped with a radio. The average worker of 1955 could afford a car immeasurably superior to that of his parents. Moreover, for the suburban family the car was essential. No other alternative was competitive in time or money for the thinly populated suburbs. In other words, the love affair with the car starts from a practical base.

*Figure 18*
AUTOMOBILE REGISTRATIONS



**Source: Derived from Statistics Canada, *Historical Statistics of Canada*, second edition, F.H. Leacy (ed.), 1983, Series T147-194.**

The 1950's car wasn't just a practical appliance. The decades immediately after the war were dominated by the belief that what was modern was good. The old dusty ways of the Victorian era or, more recently, the staleness of the depression were to be swept aside by new technologies and new designs. The old represented poverty at home and appeasement and lack of confidence abroad. The new ways and new technologies symbolized the massed technological inventiveness of Western society — the same inventiveness that had won the war.[190] This was a technological age, and the car was the item of technology closest to the average citizen.

Modernist enthusiasm was focussed as much on design as on technology. There was a belief that post-war democracies were building a new society from the ruins of war and depression. The ranch-style bungalows, the modernist buildings that dotted the cities and the grand physical projects like the St. Lawrence Seaway and Trans-Canada Pipeline reflected the faith that progress came through modern techniques applied to the physical environment. Design reflected what has aptly been termed the "populuxe syndrome" — imitations of luxury on cheaply designed mass-production items.[191] There was also an element of insecurity beneath all the rhetoric about progress and development. The ownership of family assets meant a great deal to a generation of Canadians brought up in the substandard housing of the Great Depression or in the overcrowded housing market of war.

The appeal of the car was that it so neatly combined these two deeply felt characteristics of the age — faith in technology and insecurity. On the one hand, the car, with hydro-glide transmissions, swept-fin styling and a great deal of chrome, was the primal example of the populuxe age run rampant with such suggestive names as Strato-Chief, Rocket '88, Bel Air and Biscayne, it was deliberately associated with both technology and luxury. On the other hand, the car reflected the desire of the post-war generation to raise their families with a degree of comfort and security unknown when they themselves were children. "Give Your Family Big Car Dependability," ran one Chevrolet ad, with a picture of parents and two children cruising along the inevitable open road.[192] Ford blatantly sought to capture the hopes and anxieties of the age when it wrote its own version of the history of the car in a one-page ad entitled "Escape to the Greenbelt." It was a story of inner-city decay and violence contrasted with suburban peace and tranquillity. "The whole population is moving from the stone and steel of the city toward the fresh air, the light, the trees and living space of the suburbs."[193]

As the above ads indicate, car advertising was selling a way of life. Practically without exception the car and its proud owner were depicted in country settings. Usually there was a married couple, occasionally with others present as well. The settings were always pleasant, often in the fall (when the new models came out) and often associated with such activities as picnics and sports. Typical was a later General Motors ad depicting a man fishing in an idyllic brook in a wooded glen. On the bank of the stream is his new Chevrolet. "When George Martin goes fishing," reads the copy, "he gets away from his worries. He forgets about missiles [this was 1961], taxes and the other problems that are a part of daily life."[194]

The road, the corollary to the car, appealed to many of the same values. It too was the product of technology and sought to transform the quality of life through physical development of the infrastructure. When the Gardner Expressway was first announced by Metro Toronto Council, the *Telegram* ran a one-word headline: "Whoosh."[195] The speed and freedom of the car meant nothing without the road designed to handle it.

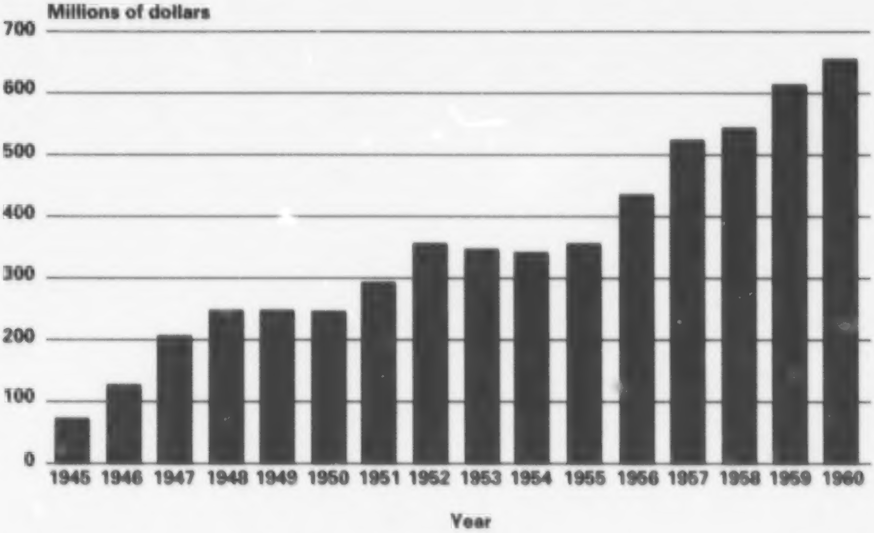
On a more practical level, highway traffic had now become so important that good roads were an important aspect of economic prosperity. Indeed, the rhetoric about the importance of a good road infrastructure is reminiscent of earlier debates about railways. A 1956 Ontario government study argued that "there is a direct relation between the level of economic activity and the volume of highway travel," and then proceeded to set up a chain of cause and effect that rested on good highways. "Increasing industrial, agricultural and mining output, as well as expansion of commerce and tourism, are all promoted by highway transport. In turn, they generate new requirements for better highway facilities. The higher standard of living and more leisure made possible by expanding production are reflected in increased motor vehicle ownership and travel."[196] A Quebec report shortly after the war made the relationship even more stark. Highways, it said, are "of primordial importance for the future development of our Province."[197] R. O. Swain, head of the International Federation of Highways, saw even more far-reaching implications during a speech in Toronto in 1954. "The highways of tomorrow will provide an efficient and effective distribution of goods and commodities sufficient to generalize better living for peoples in all walks of life." It was not just goods however. "With the highways of tomorrow will come a better and closer relationship between Canadians of the East and the members of your own family in Western Canada. Likewise, all of you will enhance life with a closer and friendly spirit of cooperation with your neighbors in the Western Hemisphere."[198]

From a later perspective what is striking in the rhetoric of roads and cars between 1945 and 1965 or so is what might be termed the "absence of doubt." In more recent decades, as we shall see, the car's proliferation has generated heated debate. Environmental concerns, urban desires to preserve neighbourhoods, and a reaction against the free-wheeling materialism of earlier decades have created a counter-image to the powerful concepts of freedom and open road evoked by the car. The 1950s and early 1960s were not given to such discussion, however. This was an age when the concept of pollution was sufficiently undeveloped that architects designed "living garages," a sort of combination family room-garage. This way one could combine those modern symbols, the car and the TV, in one room![199] The concern was not with constraining the vehicle but that highway construction keep up. One Minister of Public Works summed the mood up after complaining about the way in which car production had overwhelmed Canadian roads. "I do not contend that it is a bad thing to make motor cars; only that it is a bad thing that we cannot adequately serve motor cars with modern roads."[200] It is a statement that summed up the road policy of two decades.

These post-war attitudes had a dramatic affect on government policy and the state of Canadian roads. In 1945 user taxes generated $119.8 million from motor vehicles, considerably more than the $73 million the provinces spent on roads. Fifteen years later a buoyant economy and large increase in registered vehicles had increased the user taxes to more than $530 million. As Figure 19 shows, however, the provinces had increased expenditures even more, to $657 million. Thus user taxes accounted for roughly 80 percent of expenditures.

A couple of trends are apparent in these figures. First, continuing a tendency that went back to the 1920s, the provinces were assuming an ever greater share of road costs. Provincial expenditures rose roughly nine times in the 15-year period after the war. In contrast, municipal expenditures had risen only 2.25 times. Second, from 1945 to 1960, transportation-related items were the single biggest cost of the provincial governments as a whole, representing about 22 percent of total expenditures. In 1975, by contrast, health, education, and social services all outranked transportation. Truly the 1950s were the age of infrastructure improvement.[201]

*Figure 19*
*PROVINCIAL ROAD EXPENDITURES, 1945–1960*



**Source: Derived from *Canada Year Book*, 1945–1963.**

Aside from saying that this was a period of rapid development, it is difficult to describe in a coherent manner exactly what was done in the period from 1945 to 1965. One of the difficulties is that at mid-century there was a disparity among provinces in the number and quality of existing roads. Southern Ontario was already fairly well paved even before the war began. In contrast, when Newfoundland entered Confederation in 1949 it was still impossible to drive across the island and there were practically no paved roads outside of the immediate vicinity of St. John's. There were also extensive differences within provinces. British Columbia's lower mainland was also well served by roads, but much of the interior was impassable part of the year and served even in summer only by dirt or gravelled roads.

Still, allowing for some generalization, there are certain distinct patterns discernible.[202] This was a period of road improvement rather than one of new roads. The overall road mileage in Canada in 1965 was roughly the same as it had been two decades earlier. What changed was the quality of main and secondary roads as curves were straightened, surfaces upgraded and level crossings eliminated. There were also shifts of emphasis as time went on. In the first years (roughly to the mid-1950s) the emphasis seems to have been on the increase of paved mileage. The provinces sought to extend the sort of roads that already existed around large cities to link smaller cities and towns. Paved mileage in Ontario, for example, increased by some 50 percent between 1945 and 1955. Other provinces, starting as they did from a lower base, had even more impressive percentage gains.[203]

By the late 1950s the emphasis shifted back to the links around and between the large cities. Congestion on the main arteries between large urban centres had become a serious problem. In response, planners and governments looked to multi-lane divided highways, or freeways. In 1945 the only inter-city divided highway in Canada was the Queen Elizabeth Way (QEW) between Toronto and Hamilton. It had opened in 1937. Even after six years of post-war construction there was only 202 miles (325 km) of freeway in the nation, practically all of it in Ontario. By the mid-1960s the system had expanded to 1,646 miles (2,649 km).[204] Many of the highways most familiar to motorists throughout Canada were planned and constructed in the 10 years from the mid-fifties to the mid-sixties. These include Ontario's Highway 401, begun earlier but completed only in the early 1960s; the 403, linking the 401 to the QEW in Toronto; the Laurentian Autoroute, constructed in the late 1950s; the Sherbrooke Autoroute, constructed in the early 1960s; the twinned Highway 2 in Alberta between Edmonton and Calgary; the twinned highway eastward from Vancouver toward Hope; the Manitoba Ring Road and the Queensway in Ottawa.[205] Nothing was more symbolic of the changes that had taken place since the war than the appearance across Canada of these limited-access, high-speed, divided highways.

Though there is no "typical" province, the experience of Quebec in these years illustrates the type of activity that went on. Until the period after World War II, Quebec's efforts at road construction had been intermittent. There were several reasons for this. First, the number of car owners was much lower in Quebec than in Ontario. At the beginning of the war, for example, Quebec had 225,000 motor vehicles, compared with more than 700,000 in Ontario. Second, government philosophy emphasized the virtue of the parish and rural life and did not put a high premium on development that would link the countryside more closely to the town. Further, the same conservatism meant that government tended to move reluctantly into large-expenditure areas.

In 1944, however, a government commission investigated the state of Quebec roads. It found them abysmal outside the larger metropolitan areas and detrimental to trade, tourism and even to the prized rural life. There was an element of politics in this, as the Union Nationale party had just been restored to power and could blame its predecessors, the Liberals, for the ills that beset Quebec roads. Still, the report was essentially accurate. As of 1945 only about 10 percent of Quebec roads were paved, and only about 50 percent had any surface other than dirt. Likewise, only about 10 percent of roads outside of municipalities were kept open in winter. The great majority of road mileage was still seasonal, rough and inappropriate for the modern car.[206]

Such a situation was increasingly intolerable. The end of the war saw an upsurge of car ownership in Quebec, as elsewhere in the country. Even the valued rural farmer, as the government admitted, was increasingly dependent on good roads both for the marketing of goods and as a social amenity. As a result the government embarked on a program to reconstruct the roads of the province. In 1945 the budget for provincial roads was $25 million. By 1955 it was more than $93 million.[207] The emphasis was initially on improving rural roads. Created partly as patronage, partly from philosophy and partly out of necessity, the government program nevertheless accomplished a great deal. As Figure 20, which is a reproduction of the original map, indicates, by the mid-1950s major improvements had been carried on through the Gaspe region, the Saguenay region and the Laurentians. Quebec could boast that almost 25 percent of its total road system was paved, the highest in the country.[208] It was now possible to drive from new Brunswick to the Ontario border on modern, paved roads. Likewise, at least in the southern part of the province, most farmers were only a few miles at most from pavement. Equally dramatic improvements had been made in winter accessibility. By 1956 three quarters of the province's road system was open all year round.

By the late 1950s the original impetus of the 1944 plan was losing steam. The road system to the parishes was much improved, but, as with elsewhere in the nation, serious problems of congestion were developing around the major cities. Montreal's problems were especially acute. Traffic from the city northward to the Laurentians tripled between 1937 and 1954, and even though improvements had been made to the road system there, congestion was a major problem. In 1957 the government adopted a novel approach — or perhaps reinvented an old one — to resolve the growing

difficulty. The Laurentian Autoroute Authority (LAA) was formed. This was a private body that, with funds borrowed from the government, was to construct a modern, divided, six-lane highway from Montreal to Saint Jerome. LAA built the 39-mile (63 km) Autoroute by 1959 and operated it as a toll road. As with the 19th century toll road, the idea was that the public would pay for superior service, in this case a 70 mile per hour (110 km/h) uninterrupted trip to Montrealers' favourite holiday spot.[209] With the completion of this route the LAA was given an expanded jurisdiction and began construction on highways south of the St. Lawrence. Eventually a complex of autoroutes became a basic part of Quebec's road system (see Figure 21 which is a reproduction of the original map).

Quebec nicely represents the problems of uniqueness and generalization in any discussion of roads. It was unique in its governmental philosophy and in its reliance on a semi-private road authority for some of its projects. At the same time it typified the general Canadian pattern outlined above. Initially the emphasis was on expanding the network of paved roads beyond the major centres. Then, by the late 1950s and early 1960s attention shifted back to the problems of major urban centres and the congestion that had become a part of life there. Also, like other jurisdictions, Quebec responded with the freeway solution. Multi-lane divided highways with high speeds and limited access seemed to provide the key to the future.

Whether in Quebec or in other provinces, the massive transformation of Canadian highways did not take place without problems. A massive allocation of government funds and national physical resources were dedicated to highway construction in the years after the war. As one speaker said to the Canadian Good Roads Association (CGRA), the 1950s were "the most frantic period yet" in the history of road building.[210] The problem was not a lack of money. This was a buoyant time for governments and the public seemingly had great enthusiasm for road construction. A survey taken in 1954, already a year of significant construction, asked if the public would be willing to pay higher taxes to generate additional construction. The answer was two to one in favour of the idea. One Highway Minister commented, "there is no government that is held back in its road and street programs by an unwilling public or by rebellious taxpayers."[211]

The problems came mainly from the sheer demand put upon physical and human resources. Provinces, especially smaller ones, had to build up the requisite staff of experts to handle the complex engineering issues of modern

road-building. This was a time when engineers were in short supply, however, and it was often very difficult to get or keep skilled and experienced road engineers. The same was true of skilled labour. In addition, during the the Korean War (1950–53), the Government imposed allocation rules for vital goods such as steel. As a result many provinces had to delay bridge-building programs considerably.[212] The provinces desperately tried to keep up to public demand. It is hardly surprising, therefore, that pressures began to develop for the Dominion government to take an active role in highway development.

## THE HIGHWAY CRISIS AND THE FEDERAL PRESENCE: 1949–1967

Until the 1950s, federal involvement in road-building was sporadic. The various Canada Highway Acts of 1919 to 1928 had allocated $20 million to assist provinces in the years after World War I. In the 1930s roughly $30 million had been spent on a road program designed to assist the unemployed. During and after World War II, however, the federal government had withdrawn from most road construction. From 1946 to 1949 federal highway expenditures averaged less than four percent of that of the provinces. Indeed, cooperation between provinces had been much more significant than between federal and provincial governments. For one thing the CGRA had evolved into a quasi-interprovincial forum on highway policy. Provincial ministers of highways or their equivalents routinely headed the organization, and provincial funding supported it. The Good Roads Technical Council provided a liaison branch on highway specifications, construction methods and surfacing materials. There was also direct interprovincial cooperation on the necessary details of highway construction. A road to the provincial border was quite useless, after all, if it didn't connect with another road.

By the early 1950s the provinces were clamouring for assistance. Several arguments were used to justify the demands upon the federal government. First, roads on a modern scale had not been envisaged by the framers of the Constitution, and assistance was therefore needed. Second, the federal government reaped various fiscal benefits from the improved road system. Not only were there excise taxes on cars and, during the war, federal gasoline taxes, but the commerce that generated federal taxes depended on the road system being built by the provinces. As A. R. Morrison, President of the Canadian Automobile Association, said at one point, road construction has always been based on a user-pay philosophy. "Those who benefit from roads should pay for them." The Dominion benefitted and the Dominion should pay.[213] Third, there were even attempts during this Cold War period to borrow American precedents and argue that a good road system was key to national and civil defence. "Should atomic warfare break out, there is only one defence for civilian population — flight. Transportation itself is not the problem. The entire population of our cities could be moved if there were roads to carry the vehicles."[214] It is doubtful that any specific argument carried much weight. Their urgent repetition, however, did convey the sense of crisis felt by the provinces as well as the message that there would be little complaint about federal invasion of provincial jurisdictions.

The post-war years did bring greater federal involvement in road construction. At the end of World War II there was a strong inclination on the part of federal ministers and officials toward central planning. The Rowell-Sirois report still echoed in the mandarinate's ears, and at the 1945 Dominion-Provincial Conference on Reconstruction numerous plans were put forward to implement new programs. In a very practical sense, the federal government had the money. Despite the debt created by the war, post-war revenues were healthy. The Government ran surpluses nine out of the 10 years between 1947 and 1957.[215] Available money allowed the officials of the day to follow their inclinations! In other words, the general climate at the federal level was right for a positive response to provincial concerns.

The highway issue also had a specific appeal for the federal government. The Canadian highway system was, as has been mentioned, regionally oriented. This was understandable given that it was the provinces that were doing the planning. For a long time, however, car enthusiasts, road planners and federal officials had lamented the absence of a meaningful cross-Canada highway. By the 1950s it was theoretically possible, at least in summer, to make the trek from coast to coast. It was not practical, however. The east-west connections were generally weak and in parts of the country non-existent. Anyone travelling from east to west invariably headed south of the border. The dream of a national east-west highway, however, was a natural one for a generation that was nationalist and inclined toward big developmental projects.

The Trans-Canada was first mentioned in its new form at the 1945 Dominion-Provincial Conference on Reconstruction as one of many schemes for the post-war period.[216] Unlike many other ideas at the conference, though, it was not killed by provincial opposition. In 1948 a more specific proposition received support from most provinces, and in 1949 Robert Winters, the

Minister of Reconstruction, presented a bill to Parliament.[217] With support from all sides of the House, the *Trans-Canada Highway Act* became law in December 1949.

The parliamentary discussion on the bill is revealing. This was a project in which national pride and symbolism rather than commerce dominated — national unity, trade, public demand and national defence were all given as good reasons for the immediate pursuit of the highway project. Though it would never command the federal resources of its 19th century counterpart, there was a sense that the road was the 20th century equivalent of CPR. "The fathers of confederation," said one MP, "realized that the building of a railroad was a national responsibility. I believe the government should realize that the building of a trans-Canada highway is also a national responsibility."[218] This was echoed later by the minister in charge of the project. "Our undertaking is the largest East-West construction project since the building of our Canadian Pacific and Canadian National Railways."[219]

The bill itself was straightforward. As with many other federal-provincial programs, there was a cost-sharing arrangement. The federal government agreed to pay 50 percent of the costs on approved highway projects. The Department of Reconstruction was initially the federal agency involved, but when Robert Winters moved over to Public Works he took the Trans-Canada project with him. To be approved the project had to fit into the overall Trans-Canada route. Construction would have to meet specific standards set by the federal government after negotiation with the provinces. The federal government would have no proprietary interest in the highway after it was built and no responsibility for maintenance.[220] The maximum federal contribution under the bill was to be $150 million, and the completion date was set for December 1956. By the end of 1950 all provinces except Quebec and Nova Scotia had signed the agreement; Nova Scotia signed it in 1952; Quebec, in 1960. In the meantime, though, Quebec built its east-west provincial highway to the general standards set out in the Trans-Canada specifications, so Quebec's delay in joining did not really affect the progress of a Trans-Canada system.[221]

The possible rate of construction as stated in the agreement was unduly optimistic. Given the already extensive highway program in most provinces, it was impossible to shift sufficient resources to the Trans-Canada in time to complete it by 1956. Provinces dedicated resources and effort to the Trans-Canada only in proportion to the way it fit provincial priorities. Thus, for example, Saskatchewan and Manitoba saw the development of a first-class east-west highway link as highly desirable and made considerable progress. For Newfoundland the highway and the federal funds provided a much desired opportunity to have paved highway communication across the entire island, but limited local funds and the poor state of the provincial highway system made it impossible to move too quickly. On the other hand, Ontario was interested mainly in the Trans-Canada in the south and did not devote effort or attention to the difficult stretch around the Great Lakes. British Columbia faced a horrendous task through the mountains and proceeded slowly. Finally, even had the will been there, the amount of money and time needed were greater than original projections had suggested.

After early brave pronouncements on the progress of the highway the federal officials soon became worried. Unless the provinces "markedly step up their efforts," warned the Department of Public Works in 1954, very few would complete the work by the deadline.[222] By 1955 the "very few" provinces had become none, and by October of that year a federal-provincial conference was called to amend the agreement. It was a sign of the fiscal health of the federal government and its commitment to the project that it not only extended the deadline for completion to 1960 and increased the amount of money available but changed its funding formula as well. Robert Winters, the Minister of Public Works, noted that there was real lack of progress in many of the provinces on about 10 percent of the mileage. In most cases this was the most difficult or lowest priority section of highway — around the north of Lake Superior in Ontario, for example. In response Winters created what became known as the 90/10 formula: the federal government would pay 90 percent of the cost on 10 percent of the mileage within any given province.[223]

This broke the logjam. All sections were now tackled and real progress was made even on the most difficult sections. Still, it was expensive and time consuming. The federal government had to increase its contribution to $350 million in 1959 and to $400 million in 1960. It extended the deadline time and time again. In 1962 it held a lavish and much publicized opening ceremony at Rogers Pass.[224] In fact, though, this was public relations more than reality. It wasn't until the late 1960s and several million dollars more had been spent that the Trans-Canada Highway was fully completed. Still, by the time of the Rogers Pass ceremony it had finally become possible to drive through Canada on "passable mileage" from sea to sea.[225]

There were other federal road projects. With the Trans-Canada still under way, the new Conservative government of John Diefenbaker began the "Roads to Resources" program in 1958. The fiscal arrangements were the same as with the original Trans-Canada proposal: a 50 percent cost-sharing arrangement with the provinces. In a sense, however, this program was a precedent in its own right. Unlike the Trans-Canada project, which was focussed on a particular route and a particular nationalist goal, this program was open ended in terms of roads and brought the federal government into a project that was potentially open ended in terms of commitment to provincial highway programs along the frontiers.[226] It is also a prime example of what was earlier termed the absence of doubts. Neither government nor opposition nor interest group raised the sort of environmental and sociological questions that such northern projects would create in later decades.[227] Thus for the next 10 years the Roads to Resources program poured another $75 million dollars into provincial road-building schemes.[228]

The Trans-Canada project and the Roads to Resources program seemed at the time to indicate that the federal government had committed itself to a significant ongoing presence in road-building. As Figures 22 and 23 show,

*Figure 22*

**Source:** Statistics Canada, *Road and Street Mileage and Expenditure*, Catalogue No. 53-201, for years 1945–1968.

the contributions of the federal government to roads had been going up steadily in both absolute and relative terms through the 1950s and early 1960s. The relative figures are especially significant, given the fact that provincial expenditures had been increasing at a rapid rate throughout this period. More and more it looked as if the pattern of centralization that had seen road expenditures move from locality to province was continuing, this time with the growing presence of the federal government.

Yet the principles underlying federal involvement in roads were vague. Federal involvement really came about because there was the money to get involved, because there was a hue and cry for help from the provinces, and because certain major projects appealed to federal politicians and planners. Though the provinces were increasingly dependent on a federal presence in road construction, there was nothing here that was not more or less ad hoc. Should any or all of the above conditions change, federal involvement could easily shrink back to minor levels.

## THE AIRPLANE

Airline travel as a mass phenomenon is a very recent event. As of 1962 nearly 60 percent of adult Canadians had *never* been on an airplane. Even in 1976 a full third of Canadian adults had never flown.[229] Given these figures and given the high percentage of people who travelled only rarely, it would seem that even after 20 or 30 years of extremely rapid expansion the airplane was a form of transportation reserved under normal circumstances for the well-off traveller and for the business executive whose company saw the extra costs as worthwhile in terms of time saved. Nevertheless, rapid growth in the 20 years after the war provided a new source of competition for the railways. They had already lost much of their local and feeder traffic to the car. Now, at the other end of the market, the airplane was an ever more potent alternative.

Commercial airline service on a small scale dates back to the 1920s in Canada. Bush pilots ferried customers to locations inaccessible by railway or car. Municipalities developed rudimentary airstrips to encourage the development of local flight. In the 1930s business interests, including the railways, attempted to develop a national airline under the title of Canadian Airways Limited. Government had an interest in all of this preliminary activity and wanted to encourage some sort of coherent domestic system that had a chance of survival. Given this and given the dominance of the railways in passenger transportation, it made sense to organize air travel as an extension of the two giant railway concerns. The idea was that CNR and CPR would put up the capital and create something like a reorganized Canadian Airlines. That failed because CPR had no desire to move into a corporate structure involving a large Government presence. By this time C. D. Howe, the Minister of Transport, was enthused by the idea of a national airline, however, and he pushed forward an organization in which the new national airline, Trans-Canada Air Lines (TCA), would be a government body, wholly owned by Canadian National Railways.[230]

There is a large element of the ad hoc in the way this all unfolded. The Government decision to create a new nationally owned transportation corporation at a time when CNR losses were seriously affecting the national debt seems curious indeed. It can be explained only by the fact that initially there was supposed to be a large element of private capital; by the fact that the Minister of Transport, C. D. Howe, was an enthusiast for such schemes; and by the widespread assumption that the airline business was, after all, a fairly small-scale enterprise. Before the war, TCA's operating expenses were less than 3 percent of Canadian National's. During the war TCA slowly expanded operations to meet demand. Not surprisingly, such expansion was severely limited by the demands the war placed upon the economy as a whole.

Thus, at the end of the war, commercial air travel was still in its infancy. Indeed, from the perspective of the 1990s, the growth of air travel after the war dramatically emphasizes the technological and commercial revolution that has occurred in the past 45 years. As of December 1945, TCA's total fleet consisted of 11 Lockheed 14-08s, 14 Lockheed Lodestars and three DC3s. Total seating capacity for the entire fleet was 369 people! The airline carried 183,000 passengers, or one third of one percent of the number of people the railways carried that year. TCA had only 5,299 route miles (8,528 km), and several major Canadian cities were not yet served by air at all.[231]

There were good reasons for this primitive service, aside from the disruptive effects of the war. Airline travel was fast, of course, but it was still relatively uncomfortable and unreliable. None of the aircraft commercially licensed in Canada were pressurized. This meant that oxygen masks had to be broken out for flights over the Rockies. These limitations, coupled with the harsh vibration of the twin-engine piston propellers, created a real necessity for that airsickness bag (which is still there as an anachronism in modern flight). Weather could prove a serious problem for even the most hardy. Because aircraft could not climb above weather, they were often grounded by it. Longer flights, especially in winter, often arrived many hours, or even days late, if they left at all. The public responded by avoiding the plane in the winter season, contributing to an amazing 44 percent differential between summer and winter traffic in the years immediately after the war.[232] Even when there were no problems or delays, longer flights were hardly speedy by today's standards as the following morning transcontinental flight schedule for 1945 indicates.

In the years immediately following World War II, however, the airline companies moved aggressively. Both TCA and Canadian Pacific Airlines (CPA) made large-scale purchases of new equipment, though Government restrictions meant that CPA's mandate was primarily international rather than domestic. The Canadair Northstar was introduced in the late 1940s in an arrangement, partly subsidized by Government, to provide the aircraft company with peacetime work. The Northstar was faster and larger than earlier planes, with a seating capacity of 40. It was also pressurized. This allowed easier flights over the Rocky Mountains and better escape from weather patterns. The duration of flights from Montreal to Vancouver decreased from 16 hours to 13 hours. The Northstars also allowed the introduction of commercial trans-Atlantic flights, with planes travelling to London from Montreal in 15 hours by 1947.[233]

The Northstars were followed through the 1950s by more advanced planes. The 60-seat Super Constellation was first delivered to TCA in 1954. It was the largest commercial plane ever licensed in Canada and was such a novelty that some 30,000 Canadians lined up at airports when the airline put it on public display. It was followed by the Viscount (1955) and the Vanguard (1960). All of these planes represented significant improvements in comfort, cost-effectiveness and speed. Yet all were introduced within 15 years of the end of the war. In 1961 the arrival of the first DC-8s brought commercial jet travel to Canada.[234]

The investment by the airlines was supported by growing Department of Transport investment in facilities. Navigational supports, airstrips, terminals and an improved meteorological service all developed rapidly to match the changing technology and growing demands of the airplane. As Table 4 indicates, Department of Transport capital expenditures on air services multiplied nearly ninefold in the decade 1951 to 1961. By the end of that time there were 120 airports operated by the Department.[235] It was a level of subsidization that caused bitter resentment among railways.

*Table 4*

*TRANSPORT AIR SERVICE CAPITAL EXPENDITURES*

| Year | ($000) |
|---|---|
| 1951 | 8,625 |
| 1952 | 9,896 |
| 1953 | 12,141 |
| 1954 | 14,742 |
| 1955 | 25,625 |
| 1956 | 32,952 |
| 1957 | 46,018 |
| 1958 | 63,003 |
| 1959 | 64,555 |
| 1960 | 63,420 |
| 1961 | 73,534 |

The investment in equipment and airports helped create the most important statistic of all, a tremendous increase in passenger travel. Each year after the war there were new customers. TCA's 183,000 passengers at the end of the war increased to 427,967 by 1947, even before the Northstar was fully in service. By 1949 this number had increased to 648,574. By 1954 it was 1,438,349, an eightfold increase in a decade. Route miles of the airline increased from 5,299 (8,528 km) at the end of the war to 8,362 (13,457 km) in 1950. By then most major and intermediate Canadian cities had scheduled air service. Henceforth airline expansion was concentrated domestically on increased frequency rather than on new routes. The growth of international connections across the Pacific (CPA) and to the West Indies (TCA), however, expanded international mileage.[236]

As these figures imply and as Figure 24 further demonstrates, the growth in air travel was tremendous in the 15 years after the war. At the war's end, air travel was still an uncommon experience for Canadians. Senior business and government officials used it under the pressure of time. Tourism was developing, but it was still the rare family that in 1948 or, for that matter, 1953 would pack the children into the Northstar and head off across country. It required a sense of daring, above average-affluence and probably distant relatives before people thought of travelling as families on the plane. Most Canadians had never been on an airplane. By the end of the 1950s that was changing. Air travel was not yet the practically universal phenomenon it became by the 1970s. Still, it was by 1960 a common form of business travel and was seriously affecting the railway in that market. Tourism was expanding as well: families were lured by the introduction of holiday packages, southern routes and more comfortable aircraft.

Contributing to this growth, and resulting from it as well, was the rapidly declining real cost of air travel. Until well into the 1950s air fares were quite high and thus reserved for those with expense accounts or unusually high incomes. Air travel might have been faster than the train, but it was also considerably more expensive.[237] Throughout the 1950s those costs kept coming down. Economies of scale generated by larger airplanes and increasing passenger volumes meant that airlines could absorb increases in the cost of living, whereas railways could not. Thus in 1954 TCA could boast that "there has been no major fare increase by TCA since 1947" and that "It is the Company's aim, within the bounds of economic stability, to make air travel financially available to more people."[238] By the 1960s the introduction of tourist and then economy fares lowered the cost of air travel still further. Now TCA could boast that Canadians had "the lowest air fare structure in the world" and could back it up with a chart that showed the plummeting real cost of fares since the war (see Figure 25).[239]

The perception of the airplane and air travel during the years of growth was complex, though firm conclusions await full-length study. This perception combined a number of ideas, some of them contradictory. The airplane represented adventure. For most individuals the idea of airline travel was still exciting and a little daunting. Even after the Viscounts, Vanguards and especially the DC-8s made travel comfortable and routine, the memory of the earlier noisy planes, unpressurized cabins and vulnerability to weather remained in the public mind. There is also the simple fact that the idea of going up in the air was anything but routine when the majority of the populace had never done so.

This was not the image airlines wanted, and through the 1940s and 1950s their ads downplayed adventure. In fact, the advertisements downplayed the entire experience of travel. Instead they emphasized one of two things. The first approach was to stress the technological advantages of air travel. Advertisements talked about the newness, superiority and design of the latest airplanes. The second, and more common, approach was to ignore the travel experience and technology altogether in favour of emphasizing the point of destination. The message was significant both for what it conveyed and for what it ignored. The airline could take you almost instantly to a reunion with friends, loved ones or tourist spots far away. For the most part, however, they did not really pretend they would do so in great comfort or that the actual act of travelling would be a highlight of your vacation or business travel. The romance of the airline, then, was not in the mode of travel but in the destination.[240]

The message got through. By the 1960s the miniscule competitor of the 1940s had become a serious challenger to railways. There was now one airline passenger for every five rail passengers. Moreover, those airline passengers were being drawn from two very important market segments. First, the airlines were pulling away the long-distance traveller, the one least likely to turn to the car as an alternative. Second, they were drawing the affluent business traveller, the regular user both of the train and of luxury services like sleeping and dining cars. The car had done much to destroy the train's hold over the short- and medium-haul passenger. The airline prevented the railway from holding control of the long-haul market. Increasingly the railway, which had possessed a near-monopoly on land travel only a generation before, was without a certain market for its product. This meant that the passenger business, never a very profitable aspect of railways, was beginning to stand out as a very expensive activity.

Even so, airline expansion has to be kept in perspective. It would take another major era of growth before the airplane overtook the train as the most common form of intercity public transit. By the early 1960s the first great flurry of growth in air travel was over. The airlines had reached the limits of their current market, and the phenomenal increases of the 1950s slowed down to staid growth rates of 3–4 percent a year through the recessionary early 1960s. This slowdown came just as the airlines were investing heavily in jets, and the volume-based profits of past years gave way to operating losses. The expenditures, the slow rates of increase in passenger numbers and the losses all meant that the airlines had to pause to take stock through the first part of the decade. The airlines were discovering other factors affecting their ability to cover the travel market. The growing size of airplanes, the development of jet service, and the loss of passengers to continually improved cars and roads made short-haul flights to regional centres unprofitable. Technology also forced change. By the late 1950s the new, larger aircraft could not land on the runways of some of the smaller airports. As a result TCA began, for the first time, to abandon centres. In 1961, for example, it made moves to shut down routes to a number of Manitoba and Saskatchewan communities.[241] By the 1960s, therefore, the first great phase of airline expansion was over. For at least the next several years the inroads the airlines made into the intercity market were modest. Not until the 1970s did the next era of significant expansion begin. By that time the railroads were already beginning to retreat from the passenger business.

There is a final point to be made about the development of air travel and that is that there was little effort to develop an integrated train-plane system. From the beginning the planes competed with rather than extended the railway network. There is a certain irony in this, given that initially both TCA and CPA were subsidiaries of railway corporations. In part this was a reflection of Government attitudes. As Studnicki-Gizbert has noted, transportation policy in Canada was "modally oriented" and often seemed designed to keep the various services separated rather than integrated.[242] In part this may have reflected the traditional view that railways were too powerful and needed control rather than extension. At any rate, despite the existence of the Department of Transport and despite the nominal ownership of TCA by

CNR, airports and air services developed apart from rail services. Even the partial exception of CP's fleet of ships, trains and airplanes made little difference to the outcome. The ships were being sold off, and the passenger rail service was declining in frequency and importance.

## THE POLITICIZATION OF THE RAILWAY PASSENGER ISSUE

Perhaps surprisingly, railway passenger service was not a particularly sensitive issue until well after World War II. Of course people had always wanted railways to run in their communities or regions, and the assumption had been that such lines included adequate passenger services. There was also a recognition by the railways that passenger services of high quality were expected. If the railways forgot, they were quickly reminded. Thus when CNR president Donald Gordon considered reducing transcontinental service after the war, he backed off because it hurt the public image of the railway to even consider such cuts. "Its impact on our freight service was much greater than expected. We saw that our analysis of what might be called the psychological effects of our cancellation had not been good."[243] Nevertheless, until the 1950s neither the railways nor Government focussed on passenger traffic policy. It was an issue largely buried within the more contentious problem of freight. Once the question of passenger rail did emerge as a distinct issue, however, it quickly became politicized. For underlying it were not only economics and local community service but also highly volatile regional and nationalist sensitivities. These sensitivities shaped the railway and government response to the new competitive era that existed and led directly to the current policies and problems of passenger rail.

The relationship between passenger service and regional grievance is especially important in understanding what has happened since 1950. Of course, regional concerns have always played a part in railway policy. As we saw earlier, the Canadian government gave support to the Intercolonial, the Prince Edward Island Railway and CPR in response to regional concerns. Even after the railways were completed, regional politics often seemed to be railway politics. Yet, except for the past few decades, passenger service was not a part of this debate. Only as that service went into decline did the regions of Canada make the issue of adequate passenger service a matter of regional equity. Once they took up the issue, however, they could draw upon a rich tradition of regional rhetoric about the proper role of railways.

They could also point to policy precedents in which railway activities had been constrained in the name of regional concerns. That tradition involved freight rates; accordingly, discussion of passenger transportation and regional grievance must begin not with passengers at all but with freight.[244]

Both the Maritimes and the West have been very much involved in the regional criticisms of the railway system and of Government policies toward railways. The precise timing and nature of their concerns have been different, however. In the West many of the battles were fought and resolved before the turn of the century. From the beginning there was a tremendous dislike of the monopoly position of CPR. The lack of competition allowed the railway to make arbitrary rules on, say, loading and unloading grain unless the Government intervened. It also enabled the railways to set rates much higher in the West than in the East. In the 1880s, for example, general freight rates in Manitoba were about 50 percent higher than in Ontario. There were also a great many complaints about the absence of branch lines. CPR's policy in this area reflected a sensible, even cautious, policy of building only as traffic warranted. To the pioneer settler or local business on the frontier, however, the railway was the lifeline to the outside world, and it was natural that they would press for more rapid extension of the railway network.

By the beginning of the 20th century the West had achieved many results from its continual political agitation. The Crowsnest Pass agreement in 1897 set fixed rates (the Crow rates) for the hauling of grain and eased Western concerns in that crucial area. At the same time, the government further recognized the national importance of the relationship between the railways and the wheat economy by passing such legislation as the *Manitoba Grain Act*. Then, of course, the new transcontinental railways broke the monopoly of CPR and increased the area of the region easily reached by railway. By the 1920s the West was relatively well covered by branch lines, and though everybody loved to hate CPR, Western grievances had turned to other issues.[245]

In the Maritimes the timing was different. Discontent with the fruits of Confederation had created an on-again off-again series of complaints about regional issues. That discontent, however, had abated somewhat in the prosperity of the Laurier years and, at any rate, had never been focussed on the Intercolonial Railway in particular. By the 1920s, however, the grievance was much worse. The Maritime economy was shrinking relative to the rest of Canada, and while other parts of the country enjoyed a reasonable prosperity by 1923, the Mariti[illegible] remained mired in recession. The situation had deteriorated so bad[illegible]oth political and economic terms that a royal commission (the Duncan Commission) was appointed to investigate Maritime grievances.[246]

By now the Intercolonial Railway was very much a focus for Maritime discontent. This was due partly to the animosity generated by freight rate changes shortly before World War I and partly to the absorption of the railway into the new CNR system. There was more to it than that, however, for the railway was a symbol of what Confederation had promised to the region and not delivered. This view, which remained fairly constant, was neatly summed up by a Nova Scotian submission to the Duncan Commission.[247] Whereas, the presentation concluded, the Province of Canada had numerous reasons to support Confederation, Nova Scotia had only two: "1. That an Intercolonial railway be built." and "2. That in general, and specifically as a result of the building of that railway, these provinces were to share in the internal commerce which the creation of the Dominion was intended to promote." As the trade was not up to expectation and as, indeed, the Maritimes had declined economically since Confederation, the region was entitled to further support on "equitable and national grounds."[248]

The claim is an interesting one, for it ties the fate of the railway and the charges by a railway not to a specific legal argument but to an historical intention or assumption. It was no longer sufficient that the railway was built and operated; it should be built and operated in such a manner as to overcome regional disabilities. The concept of the railway as a political instrument of regional equalization is clearly expressed here. Moreover, the principle was accepted, at least implicitly. In the wake of the royal commission the Dominion government passed the *Maritime Freight Rates Act*, which directly subsidized Maritime railway shipments as a part of the national arrangement.[249]

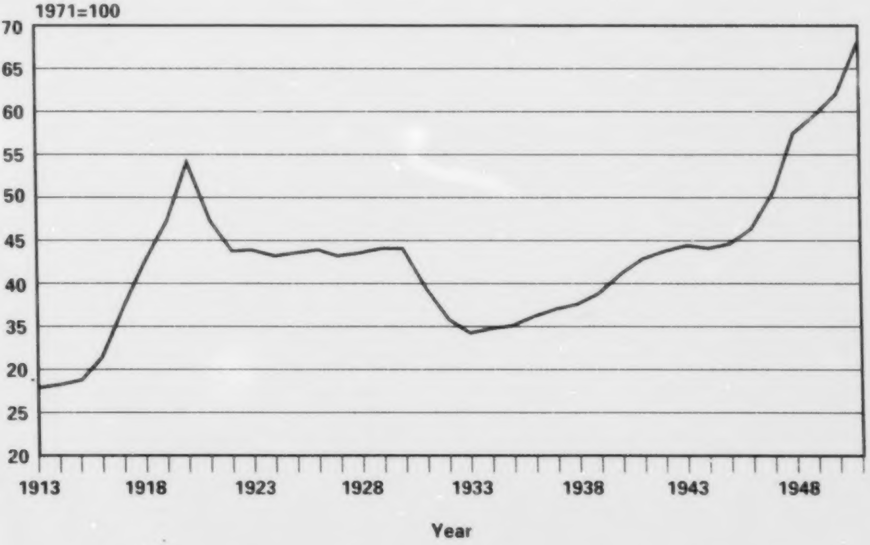
The Crow rates and the subsidy clauses in the *Maritime Freight Rates Act* therefore were precedents for treating railway charges not as instruments of profit and loss but as national policy instruments in the face of regional concerns. Nor was there any doubt about the right of the the Board of Railway Commissioners to determine both freight and passenger charges. In so doing they took "equitable treatment" and other such issues under consideration. Generally, however, the Board did not see its mandate as extending in a very broad way to issues of regional equalization. Nor did it see that as something for which the railways were responsible. "Railways are not required by law," it wrote in one decision, "and cannot in justice be required, to equalize natural disadvantages such as location, cost of production and the like."[250] There were thus two somewhat antagonistic principles at work within the governmental and public perceptions of the railway's role. All agreed that equitable rates were desirable, and this was worked towards throughout the 20th century. At the political level, however, and especially in the East and the West, railway rates were seen as instruments of a broad national policy that transcended the interests or rights of the individual corporation.

After the Duncan Commission the whole issue of freight and passenger rates became less controversial. This was due in large part to the simple fact that rates were not increasing. In the wake of the inflation of World War I there had been a series of rate increases approved by the Board of Transport Commissioners. Thereafter, however, the regulated passenger and general freight rates remained unaltered. (The first-class passenger rate was 3.45 cents per mile except in the mountains, where it was 4 cents a mile.)[251] The maximum proved profitable for the railways as the general price level declined after 1920. During the Great Depression, of course, railways found they had to lower rates much below the maximum allowable in order to generate business. During World War II, as we have seen, wage and price controls were in place. Besides, the railways made a healthy profit within the existing standards. Thus, though there was a regulatory system, the rate levels had been set so generously in the 1920s that in effect market rates, not regulation, determined passenger and freight tariffs between 1921 and 1945.

After World War II all that changed. As rates again became unstable they again became more political. As wartime price controls came off, inflation increased and for the first time the price index rose above what it had been just after World War I. The Korean War, which began in 1950, added to inflation. As Figure 26 indicates, for the first time since the years immediately after World War I there was a significant increase in the cost of living in Canada. Two additional factors made this increase in prices worse for the railways. First, there was a growing discontent in the workforce. In the immediate post-war years a series of labour disputes disrupted railway traffic and increased labour costs. Second, the railways were faced with daunting capital costs. Deferral of capital purchases during the Great Depression now came back to haunt the companies. In addition new technologies, such as efficient diesel locomotives, appeared necessary if the companies were to operate efficiently. The conversion process, however, would be an expensive one.

The old standard rates quickly came under pressure in such circumstances, and the Board of Transport Commissioners was faced with a series of requests for adjustment. There were freight rate adjustments of 21% in 1948, 8% and then a further 16% in 1949, and 20% in 1950.[252] The increases reawakened the regional concerns that price adjustments had always brought forth. When the freight increase went before the Board in 1948, seven of the nine provinces objected. Both national parties passed resolutions expressing concern, and the Government responded by appointing a royal commission on transportation (the Turgeon Commission).

*Figure 26*
*CONSUMER PRICE INDEX, 1913-1951*



**Source: Statistics Canada, *Historical Statistics of Canada*, second edition, F.H. Leacy (ed.), 1983, Series K8.**

The Turgeon Commission was the last one in which passenger issues remained marginal. As it noted, there were only a few isolated complaints about the quality of passenger service, largely from the island provinces, and one complaint about passenger fares from British Columbia that cited the mountain differential rate built into the standard fare. In this latter case, however, the railways accepted the idea of abolition and the differential rate soon disappeared.[253]

Despite the limited attention it gave to passenger transportation, the Commission is of importance here for two reasons. First, the Commission marked the return to the political arena of the hotly contested battles of the 1920s on regional equity and railways. Much of the same rhetoric was used and, if space allowed, one could show how provincial submissions returned to practically all the concerns of the earlier years.[254] The origins of the Commission, which as it somewhat tartly pointed out were definitely political, demonstrate what one critic has termed the "ideology of freight rates."[255] Second, the Commission is important because in its recommendations it supported a principle that in recent years had been used by the railways in their application for freight increases — cross subsidization. The sharp rise in expenses and the decline in passenger services were a growing concern of the railways immediately after 1945. At that time they did not seem to have had any intention of eliminating or even sharply reducing passenger services. What they did do, however, was argue that passenger service losses should be considered in freight rate increases. Freight rates, in other words, should subsidize the passenger service. The Commission agreed. "The freight and passenger services are essential and if the passenger fares cannot be raised to produce sufficient revenues to enable the passenger traffic to pay its own way the freight traffic must bear the burden."[256]

There are several points of interest in all this. First, the regional position on passenger transportation was negative: both the Western provinces and those in the Maritimes saw lower freight rates as more important than the railway subsidization of passenger service. This continued the long-standing practice of emphasizing freight while taking passenger service for granted. Second, the Turgeon Commission represents a break from the past in that the railways were now becoming concerned about their rising passenger deficits. That anxiety had prompted the railways to at least raise the question of subsidization of their passenger service. Third, all the parties involved seem caught between older and newer conceptions of the transportation industry in Canada: the traditional view of railways as a monopoly to be controlled was challenged by a newer view that railways were a declining industry, faced with fierce competition and a shrinking percentage of the transportation market. Regulation designed to control a monopolistic industry was now turning to subsidy issues in the face of a troubled one. Amidst all this, as A. W. Currie pointed out, the Commission "displays the confusion of objective which has characterized the history of transportation in Canada almost from the beginning." Were railways businesses, entitled to maximize profit and pursue corporate goals, or were they agencies of social well-being in which profit was secondary?[257]

Through the 1950s more and more policy makers began to realize that the competitive position of the railway had indeed changed and that this was especially true in the case of passenger services. Previously, the public had not lobbied strongly on questions of passenger routes and the Board of Transport Commissioners as well as the politicians had generally accepted railway decisions on the services to be provided, increased or dropped. All that, however, had rested on the assumption that the overall level of passenger service was likely to remain the same or improve. As it became apparent that services were shrinking affected communities, the press and apparently the public at large became more insistent that the railway should be viewed as an essential service. Cases for reduction of service or abandonment proceeded through channels only slowly and with great outcry. This left the railways caught between irreconcilable forces. Passenger services were becoming more and more of a burden. By 1958 the railways estimated their annual losses on passenger service to be more than $56 million.[258] It was no longer feasible for railways to absorb such losses or for adjustment of freight rates to cover it. On the other hand, the slowness of the regulatory system prevented railways from adjusting services in an attempt to maximize efficiency. Uncertainty discouraged investment in new plant, and the problems of discontinuance made introduction of new passenger routes a very dubious proposition. The railways remained committed tc passenger service, but for the first time in the history of the nation there were worries that railway passenger service might be unable to compete succcessfully in the intercity market.

This was clearly recognized by a royal commission on transportation established under the Diefenbaker government (MacPherson Commission). Though freight rates and their increase were the basic reason for the appointment of the Commission, it, unlike its predecessor, found a great deal of public concern about the quality and future of passenger services. Numerous municipalities and interest groups complained that declining service, actual or planned, threatened their well-being. At the same time there was also a feeling among witnesses that passenger services were too costly and that something had to be done to rationalize the system, though usually at somebody else's expense.[259] For their part the railways pushed hard to encourage a facilitated system of service abandonment and, where services "are held to be necessary in the public interest," to develop Government subsidy programs.[260]

In attempting to sort out all the concerns, the Commission started with a point not fully understood by the earlier Turgeon Commission. The problem, it concluded, was that both the Government and the public were behind the times in their conception of railways. Railways were no longer the giant monopolists of former years but faced instead a very competitive environment. Yet the regulatory system, the political arena and public pressure all worked against any flexible response by the railways. This was as true in passenger services as in freight.

> In this [adjustment to competition] they were handicapped, not only by federal regulatory requirements, but also by public pressure which customarily took the form of intense resistance to the dislocations which might be occasioned by these adjustments. For example, such matters as the removal of passenger services operating at a loss or the abandonment of unprofitable branch lines proved virtually impossible to decide with reference to normal commercial operation.

At another point the Commission noted pointedly that the railways are accused of deserting communities by withdrawing passenger-train service, when a more objective view would be that the communities have deserted passenger train service.[261]

If Canadian transportation were to adjust to the requirements of the last half of the century, the Commissioners concluded, the railways had to be given increased flexibility. They were no longer dominant in transportation and indeed, in passenger services, were now minor participants. If they were to continue to have any role in that area they must be left with the freedom to invest where they could make money and to get out of the business where there was no money to be made. The whole thrust of the Commission was thus toward deregulation and, to the extent that regulations continued, a recognition that railways should no longer be singled out for regulation not faced by other carriers.

Yet, in a significant qualification, the Commission drew upon an idea that the railways themselves had argued. Canada had always faced the dilemma of requiring certain transportation services when the market itself did not justify such services. The response had traditionally been Government support in one form or another. Now that rail passenger services seemed to be in difficulty, it was only natural to apply the principle to that sector. This would be done in two steps. First, said the Commission, there should be a transitional period of four years in which the railways would be subsidized for moving slowly to rationalize services. Such subsidies would run from $62 million in 1961 to $12.4 million by 1965. By the end of that period, however, much of the passenger service in the nation was expected to disappear. Second, railways would thereafter remain on a more selected range of potentially profitable lines and would be subsidized indefinitely on those crucial passenger lines where "no reasonable alternative public highway exists."[262]

The MacPherson Commission is significant in the history of Canadian transportation, for it marked a bold departure from past thinking. First, it challenged many of the myths about the power of railways and the public complaints that railways must provide adequate passenger services. Railways were neither as powerful nor, given modern public habits, as essential as had been previously argued. Accordingly, the Commission accepted the railways' complaints about being forced to continue services that were no longer required or profitable. Second, in the name of the public interest, the Commission altered the nature of subsidies to passenger services. Cross subsidization from freight to passenger services would not be favoured in the future. Instead, the subsidies would be direct, with the Government accepting the responsibility and the taxpayer footing the bill in instances where services were thought essential. The combination of public subsidy and service reduction practically guaranteed that passenger services, which had so recently become politicized, would remain highly controversial in the future. At the same time the assumption was that railways would significantly rationalize passenger services. The up-front subsidy should ensure that the public and politicians did not get too carried away preserving non-essential passenger trains.

Things did not work out as neatly as the MacPherson Commission or its supporters had hoped. The minority governments that characterized the 1960s hindered the introduction of new legislation and discouraged bold steps. Amendments to the *Railway Act* were prepared under the Conservative government in response to the MacPherson Commission. In 1964, under a Liberal government, a version of this bill was actually introduced in the House of Commons, only to die in committee. By that time the new Minister of Transport, J. W. Pickersgill, took the logic of the MacPherson Commission one step further. If railways were no longer the dominant form of transportation in Canada, it made little sense to deal with the problem by looking only at railways. By 1966 the Department of Transport was ready with a complicated bill designed not only to deal with the specific problems of the railways but also to create an agency that could look at the issues of transportation from an integrated perspective.[263] The result was the *National Transportation Act* (NTA), which became law in 1967.[264]

In principle the NTA adopted the concepts put forth by the MacPherson Commission as modified by subsequent public pressures and political concerns. Those modifications, however, proved to be significant. In terms of passenger transportation the Act extended the principle that the public interest had to be weighed (through hearings before the newly constituted Canadian Transport Commission [CTC]) before steps were taken to abandon branch lines or passenger services. Then, if service was deemed to be necessary despite losses, the government was obligated to pay 80 percent of such losses.

There were also important departures from recommendations of the MacPherson Commission. First, the Commission had not envisaged a "super-agency" to handle transportation matters. Second, the MacPherson Commission had clearly intended that Government support of passenger routes come into play only under relatively extreme circumstances, "where no alternative exists."[265] The NTA took a more open-ended approach, however, and included such considerations as "future transportation needs" and the politically loaded possibility of appeal to the Governor General in Council.[266] Related to this, the MacPherson Commission had not considered partial subsidies, but the drafters of the legislation were concerned that total subsidization would lead to profligate attitudes on the part of the companies. It was uncertain whether the Government, faced by contradictory arguments from the public and corporations, had decided the NTA subsidies were largely transitional to allow the rationalization and abandonment of passenger services or part of a national commitment to low-cost, publicly supported rail transit. What was certain is that with the NTA the new reality of intermodal competition and an ailing passenger rail sector had been recognized in law.

## 6. THE MODERN ERA: 1967–1990

The years after 1967 mark the most recent phase in the history of Canadian transportation and transportation policy. The many battles that have been fought over passenger transport in these years pose a danger for the historian. Never in the history of the issue have so many papers poured forth from the corporations, lobby groups and especially government. They range from careful and detailed studies of technical issues by the new Research Branch of the CTC to wide-sweeping generalizations about the importance of service by politicians protecting local constituencies. Yet from an historical perspective the period from the passage of the NTA until now is extremely brief. It is important to step back from the trees (or ex-trees now converted into memos) and try to single out the major landmarks and trends of the last 20 years.

From this more remote perspective, four things happened that set the stage for the various debates. First, within a very short time it became apparent that the Government was not going to apply the NTA subsidies stingily. The new CTC and the Government were cautious in their approach to railway abandonment.[267] Second, the railways finally abandoned any hope that the passenger business could be revived. Third, the annual cost of the subsidies increased much more rapidly than had been expected. By the early to mid-1970s the Government was seeking to extricate itself from the subsidy system. Ministerial decisions in 1976, 1981 and 1989 to reduce passenger service reflected this Government desire to rationalize passenger rail and, not incidentally, to reduce the subsidy levels. Fourth, while the Government was searching for a solution to the ever more expensive rail passenger service, a new ambivalence was creeping into policy on roads and cars. Energy crises, pollution concerns and other issues meant that an improved highway system seemed a dubious alternative as a form of passenger transportation.

All of this activity led to considerable comment from a public that talked in one fashion and acted in another. People weren't leaving their cars to return to the rails, but they continued to see passenger rail service as desirable and viable. There was a continued attachment to railway travel even among those who rarely or never took trains. The image of the railway corporation as the rapacious monopolist of yesteryear also created scepticism about railway motives in abandoning passenger service. Had they really tried to make it profitable? Was the bad service perhaps a deliberate response to subsidization? There was also confusion because the continued success of European railway systems and the increasing success of the Amtrak system in the United States seemed to contradict the Canadian experience of the last 20 years. Each attempt to cut back passenger rail service brought an angry response. It is thus in this modern era that the dichotomy between public attitudes and Government policy is most pronounced. It is in this era as well that there is a sharp gulf between the public consumption of passenger rail services and public support for the continuation of those services.

Another characteristic of the modern era has been the increasing influence and importance of other carriers. The airline industry went through another period of growth, and by the 1980s middle-income Canadians routinely used airlines for long-distance trips. For business it had become the standard mode of travel, even for relatively short distances. At the same time the automobile became ever more ubiquitous. Between 1961 and 1975 motor-vehicle registrations doubled, to one vehicle for every two Canadians. Theoretically, everybody in the nation could have been travelling in a car at the same time and have left the back seat empty! By the late 1970s all but the poorest of Canadian families owned cars.

Such patterns are apparent only in hindsight. In 1967, nothing was yet certain. Though there were accusations that the railways were deliberately chasing passengers away, every indication is that as of 1967 the railways were still attempting to make passenger service viable.[268] Beginning in 1963 CNR undertook a number of initiatives, including a flexible system of pricing known as the "Red, White and Blue" fares. These were designed to encourage off-peak travel at lower cost. A variation of the idea was soon adopted by CPR. Both railways upgraded their transcontinental service during the decade. CNR also spent considerable money and effort trying to draw traffic on the heavily travelled Toronto–Montreal corridor. The introduction of the *Rapido* in 1965 made the route, at least according to the Company, the "fastest train passenger service in North America for a comparable distance."[269] Plans for a new Turbo train called for a further reduction in time by the end of the decade. There were also inventive new partnerships emerging as provincially subsidized commuter systems appeared in Ontario. The GO system, first appearing in 1967, marked the reappearance of an older role for the railway — carrying short-haul commuters. Commuters would form an ever-greater proportion of total train ridership through the 1970s.

There were also hopeful signs that the long decline of ridership was coming to an end. In fact, after a generation of decreases, the late 1960s saw an actual growth in the number of passengers carried (see Figure 27). A growing population, especially the large youth population of the 1960s, needed public transportation. From a low of fewer than 19 million riders in 1961, numbers increased to more than 24.5 million in centennial year. Over the next several years those numbers remained more or less stable, fluctuating between 20 and 25 million or, to put this in perspective, about one trip per year per Canadian.[270] Finally, the NTA system of subsidies *seemed* to be working as the MacPherson Commission had intended despite the cautious approach taken toward abandonment of services. In the late 1960s and very early 1970s subsidies to railways declined consistently. By 1971 railway subsidies for passenger travel had been halved to $53.9 million.

Yet all of this proved illusory. If there was ever a chance that passenger railway travel could be retained while the subsidy system was phased out, that chance disappeared with the changing economic fortunes of the 1970s. From World War II until the later 1960s Canada had experienced one of the greatest periods of sustained growth in its history. Any recessions were brief and not too severe. This meant that passenger transportation policies, whether in the public or private sector, were formed against the background of expectations of continued economic growth and prosperity. Then, in the early 1970s, the period of prosperity faded away. The 1970s were to be marked by growing "stagflation."[271] For the next decade economic growth remained unsteady and significant inflation created instability. One component of this stagflation was especially important to the transportation sector. The large-scale increase in energy prices in 1973 had ominous implications for transportation. Travel (or the carriage of goods) became more expensive relative to other activities, and Canadians curtailed travel or sought ways to make it more economical.

All sectors of the transportation industry were hurt by stagflation in general and by the energy-price shock in particular. The airline industry experienced some of its worst years ever in the early 1970s, and both the number of passengers and number of passenger-miles decreased — a very rare event in an industry known for growth.[272] North American car makers laid off thousands of workers. Consumers turned increasingly to smaller, cheaper and more gas-efficient cars. The airline and car industries, though they might suffer in the short term, operated from a position of relative strength. Their technology was still in demand. Car registrations did not decline, though people moved to smaller vehicles, and after the short retrenchment of the early 1970s, airline ridership again began to increase.

Long after the immediate impact had worn off, however, the energy crisis affected discussions of transportation in Canada. The concerns about conservation that the crisis awakened accentuated a public and official shift toward the automobile that was already under way. People would not give up their cars to any great degree, nor did the 1950s imagery of freedom and status disappear. However, a counter-image was now developing that emphasized the negative side of a society dependent on the automobile. A series of events, from safety concerns through energy and pollution concerns, meant that the "absence of doubt" that characterized public investment in roads in earlier decades disappeared. In the last couple of decades there have been all sorts of doubt.

There had always been some critics of the suburban mythology, and the lamentable safety record of cars had been a cause of concern in the 1950s as much as in other decades. In those years, however, the reply to the critics was not to fetter the car but to design it or its transportation routes better. Modern highways would provide greater safety and better separation from local streets and generally improve the quality of life. Underlying these attitudes towards progress through to the mid-1960s was the belief that technology was a positive force. The unleashing of corporate and governmental inventiveness would, as was discussed earlier, improve peoples' lives. By the late 1960s this was an increasingly challenged proposition. For the age was, in many ways, dedicated to a cynicism about material progress and to the developmental orientation that had gone before. The North American automobile, as the symbol of the modernism and technology, was bound to come under criticism.

The critique came in stages. Initially, the car lost some of its personal glory as a symbol of technology's benefits. The North American automobile, so glorified by an earlier generation, turned out to be a shoddy example of technology. The publication of Ralph Nader's *Unsafe at Any Speed* in 1965 helped create a new ambivalence toward the North American car.[273] Technological progress, said this new perspective, was largely illusory — a matter of design and gimmicks. Underlying it all was a cavalier attitude toward such basics as safety and reliability. People still loved their cars but they were no longer certain they could trust them.

A second source of concern arose because the pressure for highway development was moving to the cities. Municipal expenditures on streets continued to climb in the late 1960s even as those by federal and provincial authorities levelled off or declined. Yet the car posed real problems to urban life. The vision of gargantuan expressways bisecting city centres was increasingly unacceptable. From the politicians' point of view it was too expensive. At the unofficial level, citizen resistance grew as city neighbourhoods feared they would be sacrificed in the name of suburban traffic flow. The highly publicized fight to stop the Spadina Expressway in Toronto in the early 1970s and the debate over the "Third Crossing" of Burrard Inlet in

Vancouver made it apparent just how politically charged such issues could become.[274] Thus the combination of urban problems and contemporary sensibilities made the automobile-oriented transportation system seem increasingly dubious, at least in and around the big cities, by the early 1970s.

Neither Nader's crusades nor the urban concerns of the early 1970s, however, had as much impact as the energy crisis of 1973. Then critics of the car could claim not just that the vehicles were badly made or that urban congestion was a problem but that the very act of driving a car was socially destructive. Numerous popular books proclaimed that the energy crisis had brought the North American automotive dream to a crashing halt. One work, attacking the automobile society upon which North American development had been based for the last quarter century, even gained the imprimatur of the Governor General in the form of a foreword. It was a sign of the times.[275] So too was the new image of the car. From the symbol of freedom it had become the metaphor for rapaciousness and inefficiency. "I should like to dedicate this essay," said one critic in a book aimed at engineers, "to the majority of mankind which has no hope at all — and, I sincerely hope, no ambition, of owning an average American car. This paragon of ecological virtue has an astonishing capacity for swallowing non-renewable resources. Quite apart from its contribution to the death rate, air pollution, noise and blighting of the city and countryside, the typical U.S. car spends much of its time transporting 1.5 people."[276]

Criticism also moved inside government circles. The official Canadian position became, at least implicitly, anti-automobile. Energy conservation was, for at least a decade, a matter of official concern and exhortation to the public. An Office of Energy Conservation was established, and the Canadian government threw its support behind measures to conserve energy. The automobile was, as everyone knew, something less than energy efficient and therefore governmental efforts at energy conservation meant government efforts to downgrade the place of the car in Canadian transportation. Federal departments like Energy, Mines and Resources warned that Canadians must abandon their dependence on the car and move "from single passenger cars to multi-passenger cars, buses and trains, and greater use of public transit systems."[277] A Department of Transport study referred to the car as "the most dangerous mode [of transportation]; a major source of congestion in high density areas; inefficiently used in terms of loads and peak periods; the largest source of pollution and energy consumption;

and most subject to weather vagaries."[278] The Science Council of Canada wrote a series of reports through the decade that urged the preservation of alternative forms of transportation and warned of the impending crisis in energy supplies.[279]

We could go on with examples but the point is fairly obvious. In Canada as in the United States the basic perspective on the car had changed.[280] The critics, previously in a minority, had now become the prevailing wisdom. That wisdom could be summed up to the effect that even if the car was not inherently bad as a transportation medium (and that was a point of debate) the way the North American car culture had evolved was socially and economically destructive. Overly large cars — often used by single passengers — vast freeway systems and excessive commuting distances had created problems of safety, urban pollution, energy depletion and social dispersal. Some of these issues could be ameliorated by better and more efficient cars, but the preferred solution was alternative transportation systems. Certainly none of the problems could be solved by building more freeways. That only encouraged more cars.

The result was the end of the single-minded focus on cars and roads that had characterized the past decades. In Ontario, for example, the Department of Highways was, in 1971, merged into the much larger and diverse Department of Transportation and Communications. "Transportation today, however, is not confined to highways. It has acquired an all-encompassing role," concluded the final report of the old department.[281] Two events were especially symbolic, however. The first involved the Canadian Good Roads Association, which dates back to 1914 and, through the Ontario Good Roads Association, to 1894. Over the years it had been the centre of discussion on and support for improved Canadian roads. Yet in 1970, arguing that "we in CGRA are aware that roads alone will not solve our transportation problems," it changed its name to the Roads and Transportation Association of Canada.[282] Second, Statistics Canada had, since the late 1920s, published figures on road expenditures in Canada. The beginning of such regular information had marked the new rise to importance of the road in Canadian life. In 1976, however, it discontinued the series. It was a symbolic reflection of the decline in the perceived national importance of road construction.[283]

The shift, though important, must be qualified, however. The 1970s saw paradoxical pulls exerted on governments. Despite the concern with energy conservation and despite the talk of alternative modes of transportation, the number of cars continued to increase in Canada (see Figure 28). The public was not going to be wooed away from the car, and thus governments were torn between searching for alternative forms of traffic and responding to ongoing congestion on the roads. This made transportation policy difficult to define. The prevailing wisdom was to woo the people out of their cars. In some places efforts were made, with some success, to do so. The GO train system in Ontario, for example, provides a perfect example of the shifting priorities of the provincial government.[284] GO was an exceptional system, however, based in the largest metropolitan concentration in Canada. Most places had neither the provincial revenue nor the population density to support such a system.

The rise of concern about the automobile was paralleled by declining investment in the road infrastructure of the nation. As late as 1966 *Road and Wheel*, the magazine of the CGRA, proclaimed that Canada was headed for a record year in road building, characterized "by large and more complex projects." The next year the headlines trumpeted that construction had reached $1.6 billion and that the record pace was continuing.[285] In fact, however, changes were in the air. In 1967 both federal and provincial road expenditures decreased in real terms. The provincial cut was especially severe: it was the greatest percentage drop since the great boom had begun at the end of the war. The next few years saw the trend continue. In real dollars, expenditures on rural roads would not reach 1966 levels again for more than a decade (see Figure 29). Even then the recovery was short lived, and by the 1980s real-dollar expenditures had plunged once again.

The near-disappearance of the federal government from road construction was an especially dramatic aspect of the turnaround in road policy. Once the Trans-Canada and Atlantic Development grants wound up by the 1970s the federal government was little involved in highway policy. Expenditures fell in absolute terms to only a small portion of what they had been a decade before. In relation to provincial highway expenditures they became insignificant, declining from their peak of 16 percent in the mid-60s to less than 5 percent by the early 1980s and to less than 4 percent by the end of the decade.[286] The basis of involvement had also become less unified, appearing for the most part under the Regional Development program under a series of ad hoc non-legislated arrangements with provinces known as ERDAs (Economic and Regional Development Agreements). There was nothing in size or cohesion to compare with the Trans-Canada program or even the Roads to Resources program of earlier decades.

Growing doubts about the car culture complicated the debate over the decline of rail passenger service. As issues of energy conservation and pollution came to the fore the train was looked upon relatively favourably, especially when compared with the automobile. The railways were obviously unable to continue without large- scale subsidization and yet, as Via 2000 and other pressure groups reminded the Government, the railway was exactly the sort of alternative that the nation needed if the car was to be used more sparingly. Much of the argument in favour of the train is explicitly or implicitly based on the "social costs" of the car and hence the desirability of Government support for national rail passenger service. By the mid-seventies federal subsidies of passenger rail service were generally higher than federal contributions to highway construction. This was a reversal of orientation from the 1960s. Then the federal involvement in the Trans-Canada system and the MacPherson Report's recommendation that the federal government get out of the railway subsidization business seemed to point the way to the future.[287]

Non-economic or non-direct economic arguments could be made that the railway should be preserved not in the name of nostalgia but for the social benefit it could confer.[288] Despite this, the economic instability of the 1970s was ultimately disastrous for the rail passenger industry. The decrease in travel, along with the more competitive alternatives to rail passenger service, meant that the railways' hopes of finding a core of profitable routes proved illusory. As Otto Lang, Minister of Transport in the mid-1970s, put it, "there were, in fact, no profitable routes."[289]

The absence of any profitable routes made unworkable the principles underlying both the NTA subsidy system and the CTC caution toward reduction in services. The hope had been that profitable routes could, with the assistance of conservative rationalization and subsidization, support the non-profitable routes. Now it turned out there was no cross subsidy. The railway companies were left in an economic "no-man's land," directed to maintain a high level of railway services, subsidized for 80 percent of their losses but required to pick up the difference. Moreover, even if the subsidies had been total there was still an opportunity cost. Every railway prediction was that freight traffic was going to increase continuously over the next several years. Every dollar, every locomotive and especially every mainline track that was cluttered up with money-losing passenger services prevented railways from meeting the demand on the freight side.[290] The absence of any profitable routes was equally disturbing to Government officials. The basic problem can be seen in the subsidy figures. After reaching the low point of $53.9 million in 1971 Government grants to railways began to go up. By 1973 the subsidies had increased to more than $130 million; by 1974, to $164 million. Also, an unprecedented two thirds of these subsidies were now going to passenger services. This was not something envisaged by either the MacPherson Commission or the framers of the NTA.[291]

These forces set off a chain reaction. Until now at least CNR if not CPR had maintained an interest in passenger services. By the mid-1970s, however, the railways spent most of their time trying to get out of the business. In the Government there was a growing cynicism about the future of passenger services. It was a technocratic era, and the romance of railway travel seemed to have little impact upon the Department of Transport, which looked increasingly to the bottom line cost of maintaining services for a shrinking clientele. "Described in extreme terms," said one mid-1970s study from the Department, "it would be cheaper for the government to buy a bus ticket for each rail-passenger and give it to him free of charge, than to subsidize the rail-passenger traveller as at present; and bus service is available alongside most of the rail routes involved and in the case of many routes, air service as well."[292]

Until then political leaders had been very cautious about any policy of rationalization. Jack Pickersgill had captured the flavour of the political view of railway matters when he commented in 1966 that "transportation has the capacity to arouse emotions and prejudices . . . more completely than questions of race, religion or language."[293] It is not surprising that his successors had been reluctant to pursue a policy of passenger rail reductions. The CTC, taking its cue from the political and public mood, had also been cautious in its approach to reductions in passenger service and branch lines.[294] The rising deficits and the studies within the civil service had their impact, however. By 1976 the politicians were convinced. In January of that year the Minister of Transport, Otto Lang, announced a transport policy aimed at rationalization of railway passenger service.[295] This decision, to accept the inevitable public criticism and to try to reduce the cost of railway services, is important. What Lang did was to force action on an agenda that had been in the making since the MacPherson Commission. Passenger services would be reduced and the political consequences would be accepted. A core of services, however, would be preserved and upgraded. Ever since this statement was made debate on transportation policy in Canada has revolved around the wisdom or folly of the actions put in motion that day.

Formally, Lang did two things through the policies he enunciated in January 1976. First, he instructed the CTC to look at passenger rail service with an eye to rationalization.[296] These instructions gave three basic roles for passenger trains: as short- to medium-distance carriers between cities; as commuting trains; and as transcontinental carriers providing a high level of comfort.[297] In effect, this put the emphasis on the Windsor–Quebec City corridor and on the transcontinental trains. This left the CTC with a difficult task. It did not know specifically what levels of service or subsidy the Government considered reasonable, only that rationalization was desirable. Nevertheless, the CTC responded to Lang's directive by proposing reductions in service and holding public hearings across the country. After considerable controversy and much press coverage, the CTC proposed a series of reductions, mainly affecting underutilized regional routes.[298]

The second thing Lang did was remove the burden of passenger service from the existing railway corporations. He did this by using the unusual method of an appropriation vote to create VIA Rail in 1977. In 1978 it became a Crown corporation.[299] If the Government was to revive passenger service given the disinterest of the railway corporations, such an agency made sense. It ended the pretence that railway passenger service was still a private business. The Crown corporation would, presumably, be more interested in providing adequate passenger service for the simple reason that that was its purpose. VIA was not without its critics, however. Then and since, defenders of rail passenger service have argued that VIA was without a legislative mandate, was unsupported by the Government and was thereby destined to fail to attract passengers.

The cuts and the creation of VIA were met by new counter-balancing forces. In Ottawa, and then across the country, a group of individuals drew upon a British precedent to create a lobby group in support of alternative transportation. The existence of Transport 2000 and other lobby groups ensured that in the future Government moves on rail service would face close scrutiny. The 1977 reductions in service also had an impact upon the public at large. As we have seen, the public hearings and the resultant newspaper coverage awakened public interest.[300] Certainly the hearings in 1977 generated a great deal of attention and controversy. This was especially true in the Maritimes. Both the transport needs of the region and the tradition that tied railway service to the Confederation pact made for lively discussions when the CTC Rail Committee came to the region in May 1977 to discuss rationalization.[301]

There were also forces in the public sector that began to reconsider rail service. If nothing else, there was VIA Rail. Its very purpose revolved around the provision of passenger service. Its existence, therefore, created an additional voice in support of adequate passenger service. Immediately upon organization VIA undertook a large-scale marketing campaign that succeeded in increasing ridership and operating costs dramatically in the first couple of years of operation. This emphasis not on profit but on service and ridership is reflected in the Corporation's annual reports of the first decade. These reports consistently point to the social and political significance of passenger transport. They also show that VIA is aware that its audience is the public service and the politicians rather than the shareholders of a private corporation. "Now here are we," wrote the President in the 1985 *Annual Report*, "the present inheritors of that remarkable tradition, feeling somewhat insecure or uncertain about whether the long progression is still relevant." The service still had a place however. "One can only conclude that as a nation we have not yet found the right way to think about passenger rail. Yet find it we must, unless Canada is to lose a vital link between its citizens. . . . Surely we should not break a tradition that is emotionally important to many Canadians because of its pivotal role in our history."[302]

In the meantime the public service tried to grapple with the issue. Rail passenger service was costing the public treasury a great deal of money, but the automobile's dominance continued to raise social and energy concerns. Indeed, the striking thing about Government studies in the later 1970s and early 1980s is the amount of time spent on the subject of that most anaemic of all modes, the passenger rail system.[303] In effect the controversy of 1976 and 1977 had raised in a serious way the question of the mix of transport modes in the Canadian future and had done so when the car was under greater criticism than ever before as a wasteful, dangerous and expensive form of mobility. In the latter part of the 1970s, reported the Science Council of Canada, the car "captured approximately two-thirds of the annual growth [of the transportation market], with the other third going to air travel. At a time of energy conservation this is not happy news."[304]

In the past decade the other major force driving Government policy has been the national deficit. Through the 1970s the deficit increased dramatically. By the early 1980s it was becoming a significant, negative economic force and a political issue. Simply put, cynicism about the future of rail travel drove Government policy in the 1970s. In the 1980s the despair lessened as lobby groups, VIA Rail and others began to look for ways to rejuvenate the system. Even as the fatalism toward passenger rail lessened, however, the imperatives of Government finance took over. The 1980s were not times conducive to massive and unproven investments in passenger rail technology. Instead, Government watched as total subsidies to VIA Rail increased to more than $300 million by 1980 and to more than $600 million by 1982. Attempts to reduce the deficits in 1981 met with massive public reaction, more hearings and polls that showed that the majority of Canadians wanted rail service maintained.[305] The Opposition Party commissioned its own task force and created a lively defence of railways that received considerable press and public attention.[306] The overall pressure was so great that in an equally controversial move many of the reductions in service were subsequently restored.

To some degree Government policy was floundering by the early 1980s, being pushed to and fro by contrary pressures. Public opinion ran against reductions in service, and there was no consensus among the government's advisors on direction that passenger transportation should take. Yet the rising national deficit and the rising railway subsidies prevented any sort of bold initiative. VIA Rail was widely seen, justly or not, as half a solution: a company without a mandate and without adequate funds. An Ontario task force report was especially critical, arguing that "VIA has no effective ability to operate passenger rail services in Canada, little control over systems and costs, cannot set its own budgetary priorities or effectively plan or experiment with different levels of service."[307] VIA was now by far the most expensive part of the railway system for the taxpayer, absorbing nearly three quarters of all subsidies.[308]

Against this backdrop of uncertainty, the most recent effort to break the logjam came with the newly elected Government's rapid move to alter the whole approach to passenger transportation in Canada. Feeling that the complex set of regulations and hearings inhibited innovative solutions, the Conservative government moved toward a simplified regulatory system where necessary and a deregulated system where possible. The idea was for "less regulation, leading to less government interference, [which] will encourage innovation and enterprise."[309] This policy, which was reflected in the new *National Transportation Act, 1987*, is still evolving and is therefore beyond any historical study. The new approach had effects on passenger transportation, but to uneven degrees. Rail service was not really affected that much. VIA, after all, had as its primary role the provision of passenger service rather than profit. It was cost conscious to a degree and for some time had been emphasizing "corridor services" to increase revenue. Deregulation did not change that emphasis and did not open the way to wholesale line abandonment. So long as the subsidies were maintained there was no purpose in doing so. In fact, when the next and most recent round of rail service cuts came, they did so in the traditional way and for the traditional reasons. The Government ordered the cuts made because of the increased deficit.[310] Likewise, the process of cuts engendered the same round of studies, controversy and outrage by opposition parties that had met both the 1977 and 1981 cuts.[311] All of this indicated, of course, that passenger rail service was far beyond the state where it could be considered in normal free-market terms.

There was a second effect upon passenger service, however. Deregulation had a significant impact on the airline industry. Despite the temporary setbacks in the wake of the 1973 energy crisis, the industry had seen healthy growth. Between 1972 and the mid-1980s passenger figures doubled, reaching 29 million by 1986, far eclipsing the number of train passengers.[312] The rapid shift that took place is brought into perspective by recalling that only 20 years before, five times as many people travelled by train as by plane. Thirty years before, 15 times as many did. Airline traffic continued to expand for many reasons. The standard of living had increased by the mid-1960s to the point where a larger percentage of the population could afford air travel. The improved technology and possibilities of wide-bodied jets allowed better service, as did fuel-efficient jets. Nor was flying the unknown quantity that it had been 20 years before. Most people took it for granted and used the technology freely. Increased volumes, in turn, allowed the appearance of regional airlines and smaller planes that aimed to draw smaller communities into the air network and thereby displace alternative modes of travel.

Perhaps the most important factor increasing air travel was the effective lowering of costs to the consumer with the introduction of discount fares. In the early 1970s, as part of "package vacations," the CTC allowed airlines to introduce "charter-type fares" on scheduled services in 1977. These fares, hemmed around with restrictions on booking, cancellation and time of travel, nevertheless attracted economy-conscious travellers to airlines. Then, beginning in 1979, seat sales were introduced.[313] The initial conditions became successively less onerous, especially under the trend to deregulation in recent years. Thus, even before the mid-1980s move to widespread deregulation, the CTC had given the airlines much more flexibility. As a result, rail travel and to a degree even long-distance bus travel lost much of the cost advantage they had always possessed.

When sweeping deregulation was introduced in the mid-1980s, the airline industry was by far the most affected. Accordingly, there was a great deal of scrambling as the two major carriers (Air Canada and Canadian Pacific) sought to increase their market share. There were also dramatic changes in the field as the successful charter company Wardair entered and then failed in the scheduled market. There was also the purchase of Canadian Pacific by the aggressive regional carrier Pacific Western (and later the purchase of Wardair) to form Canadian Airlines International. As well there were the rise, fall and reorganization of several regional carriers. All of this is far too recent to assess in any definitive way. Two things are apparent, however. First, the highly competitive struggle for market share brought at least a temporary lowering of real air travel costs through much of the decade, further hurting VIA's ability to compete. Second, the oligopolistic situation of the airline industry and the regulations that carefully divided up routes had provided the industry with financial security and stability for the first 40 years after the war. Obviously this is no longer the case. Deregulation, the globalization of the industry, the projected open-skies agreement and congested airports have turned stability into instability. Speculation abounds that there will be a failure of a major airline, leaving Canada with only one national carrier within a decade. It is all very reminiscent of the way in which CPR and CNR were viewed in the interwar years.[314] Certainly, no transportation system can be set up for the future that blithely assumes airlines will be able to bear the national burden any more than the railways were a generation before.

## 7. CONCLUSION: CONCERNS AND MYTHS IN CONTEMPORARY CANADA

As Canada moves into the 1990s public transportation is in a state of flux. The crisis of the railways has not been resolved, and there is still a lively debate between those who see rail services as essential to our future and those who see their abolition, at least outside the corridor, as essential to national solvency. The public seems to want better rail services but is increasingly pessimistic that this is a realistic expectation. The airline industry has probably never been so unstable as in the past few years. Corporate takeovers, the whole rise of the hub and spoke system, the controversy over the Pickering airport a few years ago and the growing congestion of places like Pearson Airport hint at limits to growth in the immediate future. Thus, though the technology of air travel will continue to be essential, it is uncertain what forms of corporate or route reorganizations will take place as the industry adapts to new circumstances. Buses continue to absorb a significant degree of travel, some of which would formerly have been undertaken by the train. Still, their services remain largely unintegrated with other modes, and over long distances they remain favoured only by those in lower economic groups. Only the automobile continues with relentless force to expand its dominance over the lives of Canadians.

This instability has led to a search for new policies, yet here too contradictory forces buffet decision makers. Lobby groups, such as Transport 2000, have continued to hammer home an effective defence of passenger rail and have been supported by other lobby groups, by opposition parties, and by other levels of government. In the meantime the Transportation Association of Canada has argued that the federal government must return to large-scale road investment if Canada's infrastructure is to be maintained.[315] The public is in the most paradoxical position of all. For it is the public's choice of transportation modes, especially its overwhelming attachment to the car, that has determined much of the policy of these years. The public is also one of the staunchest defenders of passenger rail transport. In 1981, when a series of VIA cuts were introduced, a Gallup poll indicated that a plurality of Canadians in *every* region wanted service retained or improved. Even when people were asked if they would be willing to have taxes increased to support passenger rail service, the support continued in every region except Quebec.[316] The situation had not changed eight years later. When the Government moved to reduce VIA services in 1989 a poll indicated that an overwhelming 89 percent wanted VIA continued; this time there was majority support in every part of Canada. A clear majority (54 percent) actually wanted VIA service expanded.[317]

Such support indicates that Canadians, even those who don't use the train, have a strong set of emotional attachments to passenger rail traffic. To understand why such attachments exist it is necessary to move from rational cost-benefit analysis or specific patterns of use to the realm of myth. A myth in historical terminology is not necessarily false, though it can be. Rather, a myth is a collection of beliefs and assumptions held to be true by a wide segment of the population, whether true or not. Canadian railways, because of their long history and recent controversial debates, are associated with a number of popular myths. Individual myths or elements of myths appeal to different segments of the populace and are used by different interest groups. As a totality, however, they possess a powerful collective hold over the thinking of the Canadian public and explain why policies to cut back services have been resisted so strongly.

The first and most potent of the myths is the nationalist myth. It developed around the time the Canadian Pacific was constructed. It was strengthened over the years by a combination of railway image building, public association of railway travel with "seeing the country," academic assessments of the importance of East-West links, and popular portrayals of the romance and adventure of the railway. A Gallup pollster summed up the power of this myth in response to the overwhelming support of VIA in 1989: "The trains are almost folklore in Canadian history, going back to the opening of the West and the national policy of John A. Macdonald."[318]

There are two striking things about this myth. First, though most of the railway's business and its most important national role have always been freight, it is passenger service that evokes the emotional response. It is not enough for wheat to travel East to West — people must. Second, it is striking how populist this myth is. Many of the arguments about railways are technical and are, at least in detail, for the experts and enthusiasts. The nationalist myth is something that is not determined by expertise or by the special interest groups, though of course it has been encouraged by them. It simply reappears at every point in which the public has input. The most recent example comes from the Spicer Commission's "hot line" and citizen forums. People resented the dismantling of such "national symbols" as the Canadian Broadcasting Corporation and passenger rail.[319]

Also, though all rail passenger services are lumped together under the national myth, at the real heart of that myth are the transcontinental trains. "They are," concluded the President of VIA, "a unique and historic national symbol, a means of enhancing national unity and a contributor to tourism."[320] "The closing of trans-Canada passenger service on the Canadian Pacific Railway," argued Transport 2000 recently, "is both a real barrier to communication and a symbolic attack on national unity."[321] "VIA Rail — National dream fades," trumpeted the headline in the *Toronto Star* during the most recent round of cuts.[322] Thus, public mythology can be focussed. The attachment to trains is really an attachment to passenger services and in particular to the grand tradition of the Canadian transcontinentals. Moreover, this nationalist attachment is not predicated on the belief that a rail service will save the country. Rather, it is seen in conjunction with a number of other forces as a part of the fabric of Canada.

Subsets of this national mythology exist in each of the regions. Sometimes it is purely a localized version of the national romance of railways. The 1977 cuts led journalist Jean-Paul Desbiens to reminisce about trips from Metabetchouan to Quebec City. Significantly, he saw his personal experience as part of the national experience, saying that it was "Trains: to people and to the land, a heritage. He remembers them well."[323] In most cases, as we have seen, the regional variations emphasize the relationship of that particular region and the "national compact" — a compact that includes train services. Behind this is a more general principle that in the regions emphasizes the national policy role of the railways, or what the MacPherson Commission referred to as the tradition of obligation.[324] Emphasizing this aspect of the railways subordinates profit or economic rationalization in favour of regional equity and national policy. As well-known Manitoba historian W. L. Morton testified before the MacPherson Commission, regulation of railways "was necessary to ensure that railways indeed fulfilled their role in national policy by providing the various regions of Canada with railway services on terms and rates equitable as between the public and the railways and as between the different regions of the country." An economist from

Saskatchewan saw the national myth by definition as uneconomic and therefore argued that railways should not be thought of in purely economic terms. "It is from the attempt to reorient trade from its economic pattern that most of our subsequent difficulties have arisen."[325]

A second and quite different myth exists about rail passenger service. This, for lack of a better term, might be referred to as the "if only" myth. The argument here is that in fact rail passenger service is viable if only some certain steps are taken or some previous arrangement had not been made. If only tracks were upgraded to allow faster service. If only car users had to pay their fair share of road costs. If only the railways had not charged VIA such exorbitant rates for running rights, old rolling stock and so on.[326] The list could go on, but the basic point can be made in one citation. "We agree with Transport Canada that current rail service is untenable. The erosion of passenger services is real but given the virtual neglect of the rail mode over the past twenty years, it was inevitable."[327] In one form or another all the "if only" myths rest on the belief that the decline in rail service came from neglect, bad planning or hostile, air-minded bureaucrats.[328] Also essential is the corollary belief that good planning, effort, investment and a far-sighted government can turn the decline around.

The interesting thing about this myth is that unlike the previous one it is testable in normal economic and planning terms. Cost-benefit analyses can be done on technology improvements, alternative routings, integrated stations, an altered VIA mandate and so on. What makes this a myth and not just a proposition to be tested is its endlessly varied possibilities. Either side in the debate can easily maintain a position for or against rail travel whatever proposition is proven or disproven. Other issues are simply introduced. As a parliamentary committee reported in exasperation during the 1989 debate on cutbacks, "the Committee was confronted with a plethora of divergent statistics put forward by various witnesses with great persuasion and conviction. . . . The observation the Committee would like to make is that statistics can be used to make anyone's case or position sound persuasive."[329] The statistics are just a subset of the whole "if only" debate. What is important here is not the truth or falseness of any particular assertion (though ultimately it is very important) but the very persistence of the debate. It reflects a widely held belief that neither the railways (for reasons of policy) nor the Government (for reasons of cost) has given passenger service an adequate opportunity to prove itself.

The third myth could be described as the social-benefits myth, and its characteristics borrow from both of the other major myths. The argument here is that whether or not passenger rail travel could be made profitable, it is worth the subsidy for social reasons. The 1970s argument about passenger service in an energy-conscious community that we have already discussed is a primary example of the myth of social benefits. More recently energy has become less of an issue, but another environmental issue, pollution, has replaced it as a focal point of discussion. Such environmental issues are joined by a myriad of others, some more reasonable in their claims than others. Thus, for example, train service is often seen as a means of transportation equity: the poor, elderly, and those with disabilities or from isolated communities are more likely to need the train than others. Regional equity is also involved, but more important recently has been a hinterland-metropolis approach in a more general sense. The marginal communities, whether in small-town Ontario, the Maritimes, or the North, are seen as dependent on trains in a way that large urban centres with good airports and roads are not. A 1977 editorial in the Toronto *Globe and Mail,* "Count the Social Costs Too," which condemned reductions of train service into Sudbury, perfectly illustrated this very potent concern. Cost efficiency, it said, left the Northern communities feeling "abandoned, neglected." Subsidies were especially necessary to prevent "inconvenience to thousands of small communities." Then, in an appeal to the national myth, it concluded, "We would never have built the railways if Otto Lang had always been in Transport."[330]

As was just mentioned, the social-benefits myth touches upon both the national identity myth and the "if only" myth. Canadians are well attuned to the general themes of pollution, energy consciousness and regional equity. To the extent that these themes are hammered home by supporters of passenger rail, therefore, trains become a "good thing" deserving support. This makes the national symbolism of the train all the stronger. Not only is it a part of our history, but as an institution, it still deserves support from the public purse. Likewise with the "if only" myth, the belief is reinforced that if it were only possible to measure and charge the true social and individual costs of such modes as the car, passenger rail would thrive, perhaps even without subsidy!

There are lesser social-benefits myths as well. An element of train travel is the sense of community it brings. Neither the automobile, with its privacy, nor the airplane, where people largely stay in their seats, gives the sense of interaction that the train provides. "You meet such friendly people," recounted a New York couple in Jasper recently. "We almost hated to get off the train to come here [Jasper Park Lodge]."[331] This sense of interaction and community appeals, at least in theory, to a good many Canadians, even when they do not take the train with any regularity.

Finally, there is what might be termed an "if . . . then" myth, which reflects a fear of what the decline in train service means to the community involved. It is not that the loss of a passenger train or so would actually seriously undermine the community but that the loss of passenger service is taken as part of a wider economic decline. For this reason it is the smaller cities, often in the Maritimes, that fight the hardest to retain a service. Their people do not use the service more than anyone else, but the jobs the railway provides, even if relatively few, and the symbolism involved in shutting yet another link between this community and "mainstream Canada" make railway closures an emotional issue. This theme applies equally to air services. Adequate train and air services to major points symbolize a city's status, are seen as essential to encourage growth, and are a part of the employment base of the community. It is the one area, therefore, where there may be a direct trade-off between trains and planes. Better plane service could be exchanged for reduced train service.[332]

It is beyond the scope of this paper to unravel or test the many complex beliefs contained within these three major myths. Indeed, many of them are untestable, and many others, such as the national symbolism of the railway, do not lend themselves to specific cost judgements. The point is that they exist. Some may be accurate, some not. They reflect a strongly consistent part of Canadian public psychology, however, and may explain why a transportation system such as rail passenger service, so long underfunded and underutilized, has refused to die. It may also indicate that any blend of transportation systems developed for the future will have to take into account what the public expects of its national transportation system in psychological and social as well as economic terms. Certainly that has been the case through the history of the nation. Emotion and myth were important in William Hamilton Merritt's dreams of canals, Thomas Keefer's philosophizing on railroads, the nation-building imagery of CPR, C. D. Howe's aspirations for a national airline, and the Canadian fascination with the car. Everything indicates that emotion and myth will continue to be important in the future.

232. Gordon R. McGregor, *The Adolescence of an Airline* (Montreal, 1970), pp. 8–9.

233. TCA, *Annual Report for 1947*, p. 9.

234. For very brief summary of developments in TCA see C. A. Ashley, *The First Twenty-Five Years: A Study of Trans-Canada Airlines* (Toronto: Macmillan Co. of Canada, 1963).

235. Canada, Department of Transport, *Canada in the Jet Age: A Report on a Study of Department of Transport Air Services Needs 1962–1972* (Ottawa: Department of Transport Air Services, 1962), p. 25.

236. TCA, *Annual Report*, 1945–1954.

237. It is difficult to make direct comparisons, given the different types of services involved. TCA measurements indicate, roughly, that air travel cost twice as much per passenger-mile as rail travel in 1955.

238. TCA, *Annual Report 1954*, p. 9.

239. TCA, *Annual Report 1961*, p. 7.

240. There are no detailed studies of the imagery or selling techniques of the airlines. These comments are drawn from *Maclean's* and *Chatelaine* from 1945 through 1961, as well as from more limited checks of the newspapers of the period. As John Helliwell commented to me, however, the imagery of the airplane in the North is quite different. There it was much more of a lifeline to the outside world. Equally, the mythology surrounding the Northern bush pilot takes on some of the romance associated with pioneering adventures. See John Condit, *Wings Over the West: Russ Baker and the Rise of Pacific Western Airlines* (Vancouver: Harbour Publications, 1984); Tony Foster, *The Bush Pilots: A Pictorial History of a Canadian Phenomenon* (Toronto: McClelland and Stewart, 1990).

# U.S. INTERCITY PASSENGER TRANSPORTATION POLICY, 1930–1991: AN INTERPRETIVE ESSAY

George W. Wilson*

October 1991

## 1. INTRODUCTION

The U.S. has not had anything resembling a rational, coherent or unified policy with respect to transportation in general and even less of one regarding passenger transportation in particular. Legislative changes since the late 1970s in the direction of "greater reliance upon market forces" represent the beginning of a more coherent and consistent approach but there is no certainty that this will persist. The emphasis upon some variant of the economists' efficiency criteria may turn out to be short-lived. Certainly the "economist's hour," as it has been called,[1] took a long time coming to the area of transportation policy and despite some recent successes constantly needs to be addressed, as will be noted later. Thus the characterization of the past U.S. federal government's approach to transportation policy as "A chaotic patchwork of inconsistent and often obsolete legislation [that] has evolved from a history of specific actions addressed to specific problems of specific industries at specific times" is not an unfair appraisal, all the more telling since it came from the Special Message to the Congress on Transportation by President Kennedy in 1962.[2] As late as 1979 and despite some 20 or more years of strong pressures from the economic community, backed up more or less by every president from Kennedy on, a major policy

---

* Indiana University.

study[3] could with justification still assert that the government's approach to transportation remained "an assortment of policies and programs which have been developed in an *ad hoc* fashion to achieve sundry goals or resolve various issues."[4]

This is not, of course, unique to the U.S. All countries suffer from what may be referred to as the "Grand Transportation Mystique" (GTM), which identifies transportation investments and policies as having special attributes for stimulating economic growth or solving problems in other industries. They accomplish such goals by providing lower, preferential fares or rates, expanded capacity, improved service quality and so on without regard to costs or alternative investments or policies that might often prove to be more effective and less costly. There is a belief that transport should be used as an instrument for accomplishing objectives in other segments of the economy or in the "national interest."[5] The GTM is thus a mind-set that leads governments into actions towards the transport sector that more careful thought and better knowledge would indicate to be inefficient and perhaps even counter-productive. These actions take many forms and there are numerous examples, especially in North America. But everywhere these involve enormous resources to preserve parts of a system no longer needed, to expand investment into areas of limited economic potential far ahead of potential need or demand, or to maintain a pattern of regulation that involves considerable economic waste for purposes that become increasingly difficult to explain and more difficult to justify. The GTM also encourages efforts to regulate, subsidize, operate or otherwise dabble in virtually all aspects of the provision of transport services.

To be sure, from time to time the apparent dabbling and/or expenditure may have seemed sound, perhaps sensible, necessary or maybe even "efficient." But as the economy or circumstances change, the consequences of such activities become increasingly dubious, and very costly to maintain relative to any realized benefits. The belated recognition of such past "mistakes" then gives rise to a more or less major "policy change." This study reflects upon the changes that have occurred along these lines in the U.S. with special reference to intercity passenger transportation since the late 1920s.

In Canada the major transportation policy change was identified in the MacPherson Report[6] which led to new legislation in 1967. The new policy emphasized the workability of competitive forces in Canada, especially in the post-war environment, and the resultant desirability of refraining from using any particular mode of transport, especially railroads, as an instrument of national policy. Greater reliance upon market forces was to be counted on in the interests of efficiency and, in general, economic criteria were to be emphasized and regulation minimized. Where subsidy of any kind seemed desirable to accomplish some specific public purpose, the railroads were to be compensated for the losses involved. The previous "monopoly" position treated such loss-generating activities as a kind of *quid pro quo* for past government support and which could then be readily funded by cross-subsidy from so-called captive traffic. Such internal subsidization was no longer feasible under competition and never very economically efficient.

While the MacPherson Report focussed mainly on railroads and freight, it encompassed all modes. As the Report itself noted, the "freight rate inequity problem" was its "principal raison d'être."[7] Yet the emphasis upon the pervasiveness of competition in transportation certainly was believed applicable to passenger transportation as well. Rail passenger deficits were uneconomic and to be eliminated as the public had indicated its preference for other modes of travel.[8] Intercity passenger travel was mainly an afterthought or ignored altogether in most major U.S. transportation reports that I have been asked to examine (see Table 1) except for the adverse impacts of passenger deficits on the rail freight business. But the MacPherson Report stands out among its would-be U.S. counterparts as having taken the lead in establishing a major policy shift towards the totality of commercially provided transportation. Not a single U.S. report was so far ahead of the general economic philosophy of the government at the time. In fact, MacPherson led to a consensus in favour of change in Canada and paved the way for major legislative change within six years.

Similar sentiments were brewing at the same time in the U.S. but no study or report succeeded in capturing the flavour of what needed to be done with sufficient persuasiveness or power to culminate in implementing legislation. Indeed, the requisite legislation did not even begin in the U.S. until the late 1970s and early 1980s. The various U.S. reports, studies and the like mainly reflected a growing consensus among those interested in transportation (including academics, politicians, lawyers, regulators, providers of transportation services, shippers as well as intelligent and concerned laypeople) that existing arrangements were becoming increasingly counterproductive and that alternatives were needed. References to U.S. reports in this study are mainly included to highlight the slow and tepid approach to substantive revision of U.S. transport policy compared with Canada. In only one major aspect was the U.S. ahead of Canada; Amtrak was created in 1970 while VIA Rail was delayed seven years, hardly something to be proud of under a transport philosophy stressing market forces and elimination of most non self-support services.

## THE SUBMERGENCE OF EFFICIENCY CRITERIA

It is not immediately obvious why the U.S. delayed so long in implementing the kind of change in policy that Canada had accomplished by 1967. The Canadian environment was certainly less structurally competitive than that of the U.S. With only two major railroads and air carriers, a less ubiquitous highway system than the U.S. and generally smaller domestic markets, competition in Canadian transportation would have appeared to be less workable. Given Canada's lesser emphasis upon market orientation, or "capitalism" in general, the move to deregulate a substantial aspect of the economy was a bold one that might have been expected first from the U.S., especially in an area deemed as important and historically significant as transportation. Certainly U.S. economists did not lag behind economists in Canada in their analysis of the need and enthusiasm for transport regulatory reform. Many even testified before the MacPherson Commission hearings and strongly supported the final report. Most loudly cheered the passage of the *National Transportation Act of 1967* and widely proclaimed that Canada had indeed taken the lead in developing sensible economic policy toward transportation, a lead that the U.S. should promptly follow. However, more than a decade was to elapse before the U.S. got around to serious policy revisions. Even then they were partial and modal.

Thus one of the themes to be explored in this essay is why the long delay and more important, why ad hocery with respect to transportation policy persisted for so long in the U.S. It was surely not too radical to adopt an alternative that emphasized efficiency and market orientation or at least an approach that sought to assess the benefits vis-à-vis the costs of alternative and existing policies much earlier, especially in the bastion of *laissez-faire.* Certainly the virtual ignoring of efficiency criteria prior to the 1960s in Canada and the late 1970s in the U.S., as well as the earlier timing of the pro-competitive policy in Canada, cries out for explanation. The almost exclusive concern in U.S. transportation policy has been for something vaguely defined as the "national interest" which had a heavy dose of defence in it, to say nothing of "regional development or balance." Both of these notions are deliciously vague but when mixed with emphases upon "equity," "justice," "reasonableness," "fairness," "adequacy" and so on, they defy conceptual or empirical clarity. Since the goals of transport policy were never clearly spelled out, the ingredients of policy could not be related to any purpose.

Thus for example, the first explicit statement of national transportation policy in the U.S., which appeared in the *Transportation Act of 1940* is a welter of ambiguity. It reads as follows:

> It is hereby declared to be the national transportation policy . . . to provide for fair and impartial regulation of all modes of transportation subject to the provisions of this Act, so administered as to recognize

> and preserve the inherent advantages of each; to promote safe, adequate, economical and efficient service and foster sound economic conditions in transportation and among the several carriers; to encourage the establishment and maintenance of reasonable charges for transportation services, without unjust discriminations, undue preferences or advantages, or unfair or destructive competitive practices; to cooperate with the several States and the duly authorized officials thereof; and to encourage fair wages and equitable working conditions; — all to the end of developing, coordinating, and preserving a national transportation system by water, highway, and rail, as well as other means, adequate to meet the needs of the commerce of the United States, of the Postal Service, and of the national defense. All of the provisions of this Act shall be administered and enforced with a view to carrying out the above declaration of policy. ('54 Stat. 899, 1940.)

To be sure, all policy statements are vague and general. This one at least mentions the word "efficient" but it is buried or lost amid notions of "just," "reasonable," "undue," "adequate," etc.

Under this rubric and even earlier, the Interstate Commerce Commission (ICC) for example, concerned itself about the stability of the railroad rate structure, about the need to preserve "common carriage," about the need to prevent any regulated mode of transport from driving another mode out of business or even one common carrier "injuring" another. Common carriers were to "share" markets, not compete against each other, in the search for "preservation of inherent advantages." Sometimes these *desiderata* were invoked for purposes of national defence,[9] sometimes for the needs of shippers and passengers or for something else entirely such as "stability." Transport regulation often vacillated between protecting the public and protecting the firms regulated. Too often many of the markets were preserved for a selected number of regulated common carriers thereby creating monopoly or oligopoly — like situations which were then used as justification for continued regulation. The entire airline passenger industry was effectively cartelized by the Civil Aeronautics Board (CAB) for 40 years after its formation without consideration of its competitive possibilities or in the nave belief that all transport competition was "destructive." The courts occasionally reminded the regulatory commissions that they were not given carte blanche authority to create a cartel out of a competitive situation.

At the same time, no regulatory agency was able to ensure that carrier costs were minimized for any level of output because there was no way to determine the costs or quantities of particular inputs, the technology employed or managerial aptitudes. The cost side of carriers' operations were beyond the control of regulation. In the absence of competitive pressures and with the inability to compete on a price basis, regulated transportation was inefficiently provided. If we add to this the "other" costs of regulating, such as the deliberate creation of excess capacity (for defence purposes, of course), the costs of running the regulatory agency itself, the wastes involved in the innumerable and lengthy cases designed to give "due process" to all whether or not directly involved, the diversion of managerial talent from running the business effectively to taking care of matters of regulation and so on, it is clear that the regulatory aspect of public policy, so pervasive but uneven in transportation, pretty much ignored efficiency of production.

Since the other main aspect of public policy, namely provision or financing of infrastructure, was also bereft of sensible investment or benefit-cost criteria, it is evident that efficiency considerations got short shrift. In fact, anti-efficiency sentiment was so strong that attempts to make public investment in transportation subject to such criteria were systematically expunged from any proposed legislation. Nor has there been much success in developing an efficient set of user-charges for publicly provided rights of way.

Thus while the major thrust in the U.S. over the past decade has been in the direction of market forces and efficiency, there is considerable distance yet to go in terms of public investments, user-charges and even adequate enforcement of antitrust laws to forestall anti-competitive mergers and practices. But the approach to change in transportation policy and the more overt economic goals suggest at least a conceptual clarity. There is now a greater willingness to view transportation as analogous to other industries with no unique aura or magic entitling it to special attention. The GTM has been tarnished at least. It is, and ought to be, subject to the regular impacts of supply, demand, competition, technology and so on affecting all productive aspects of the economy and judged by similar criteria. The prime goal of transportation policy should, therefore, be "Efficiency within transportation, both in terms of use of existing infrastructure, vehicles, and rolling stock . . . and in terms of investment criteria . . . deviations from which require special justification. . . ."[10]

## THE DISTINCTION BETWEEN PASSENGER AND FREIGHT TRANSPORTATION

Throughout the changes in U.S. transportation policies the emphasis has almost completely been on freight transportation. The original *Act to Regulate Commerce*, 1887 was the result of shippers' complaints of excessive rate discrimination; although written with sole regard to freight, it was made applicable to rail passenger traffic as well simply because rails provided both services. Bus service was included in the *Motor Carrier Act of 1935* virtually as an afterthought. Relatively few cases or proceedings were held in connection with bus transportation compared with intercity truck commodity movements. Even the creation of Amtrak was less a direct passenger-oriented measure than a means of bailing out the railway freight industry from ever-increasing passenger deficits. Almost all changes affecting passenger traffic have come about through attempts to respond to problems originating in the movement of freight. This is true of the MacPherson Report as well.

Joseph B. Eastman, one of the most important American regulatory commissioners ever, plaintively remarked in 1936 that "passenger service should not be considered and dealt with as an unavoidable but unwanted stepchild of railway operation."[11] Yet as far as *commercial* passenger service is concerned, aside from airline policy, passenger traffic has received little overt attention. This should not necessarily be lamented. Many of the carriers receiving most of the regulatory attention often wished they had been less "favoured." Even the airlines, overwhelmingly a passenger mode, received their early subsidies in the U.S. not on the basis of the number of passengers or passenger miles, but as "mail-pay" (that is, goods movement) contracts. The subsequent deregulation was based upon earlier arguments made for freight markets in general and preceded by prior deregulation of air cargo. The statement of national transportation policy in 1940 noted above omits explicit reference to air transportation probably because the latter deals mainly with passenger traffic. As one of the few texts on passenger transport puts it, "the subject of this declaration is really freight transportation."[12] In fact, air regulation was at one time to be placed under ICC jurisdiction but fear of overloading the Commission already swamped by being given jurisdiction over motor carriers in 1935,[13] led to creation of a separate commission which later became the Civil Aeronautics Board.

The assumption underlying the lack of distinction between passenger and freight transportation is that the differences between moving people rather than goods are not important. Furthermore the relative indifference regarding commercial passenger travel from a policy perspective is doubtless related to its small amount compared with total intercity passenger traffic. Passenger revenues were never a very large proportion of total rail revenues and ever since the ICC kept the data, from 1936 until the creation of Amtrak, rail passenger traffic, leech-like, recorded deficits which were made up from net revenues from goods movement. The massive highway programs of the U.S. and the concomitant development of the private automobile have relegated the size of the entire commercial intercity passenger market to somewhere between 10 and 15 percent of the total. The vast majority of the populace have feasible travel options somewhat independent of air but obviously independent of bus and rail, in the sense that, if the latter two simply disappeared, the *national* inconvenience would be slight.

What are the differences between passenger and freight transportation and do they matter as far as public policy is concerned?

There are some obvious differences between people and goods transportation. Service quality is more important for passengers than freight. Comfort of the ride is qualitatively different and more significant for people. It may be an overstatement but there is some truth in the assertion that "getting there is half the fun." Passengers have to be individually placed and guided to often pre-arranged seats unlike tons of coal or even packages of freight, and then must be more or less "entertained" *en route*. The terminal facilities need to be of considerably higher quality for people. Whether they had to be the opulent structures of many of the old railway passenger terminals which became landmarks in many parts of the country, a kind of North American substitute for European castles, is not clear. They must however be especially well organized to move people on and off vehicles or aircraft with a degree of convenience, care and dispatch unnecessary for goods. Baggage handling is another function that occasions special handling, extra costs and more careful organization. Unlike freight, passengers can also complain. Although freight shippers often voice their opinions of the service, there are fewer of them than there are passengers, and the complaints are likely to be of a different sort. The quality dimension of passenger service is thus likely to loom as far more important and of a different kind than for commodities.

All this suggests that passenger cost functions are likely to differ from those of freight depending upon the mode — air, rail, bus or water. To be sure, analytically there is no reason why a cost function related to an output unit called ton-miles rather than passenger-miles should differ in general shape. Indeed, economic analysis, in seeking to be general, makes no distinction among the various kinds of output or output units and remains wedded to a theory that leaves the output unit carefully undefined and unspecified. It thus makes no difference whether output is something physical (such as tons of steel, bushels of wheat, units of homogeneous widgets, etc.) or some non-storable service, (such as transportation, entertainment, medical treatment, etc.).

If no distinction is made between physical and service units in general economic analysis, it is scarcely to be expected that passenger-miles and ton-miles would get separate treatment although neither of these often-used transport measures can be construed as homogeneous. That is another and longer story that I have dealt with elsewhere and which needs no elaboration here.[14] Suffice to say that a proper conception of output units is essential not only for empirical research on both cost and demand functions but to pin-point that elusive but important concept in economics, *marginal cost*. We need to know marginal cost of *what* for pricing and costing purposes and for different qualities of any quantitative output unit. Fortunately much progress has been made along these lines.[15] But the lack of widespread concern over output units has made it easier to ignore the distinction between moving things and people. Both involve "transport" and for many that is good enough.[16]

Furthermore the nation's estimated freight bill is vastly in excess of the estimated passenger bill if we exclude private automobiles. Some estimates suggest that the freight bill is some five and a half times larger than the passenger bill and that this has remained fairly stable over the years.[17] Thus the insignificance of commercial passenger travel relative to freight movements in the U.S. may account for much of the neglect of the former and would partly explain the concentration of regulatory policy changes over time on the freight aspects of transportation. People-movement is overwhelmingly by private car and not for profit and thus not subject to the kinds of economic or business constraints oriented to competition control, profit regulation and route, back haul and other restrictions. Indeed, freedom of travel along publicly provided rights of way in one's own vehicle is taken for granted. Automobile ownership is now virtually universal in the U.S. Yet this was not always the case and during earlier periods, say the 19th century, freight still ruled the aim, end and process of policy formation.

Hansen has remarked that the "distinction between freight and passenger transportation was often obscured" but that in the "developmental context" this was of little importance. In the 19th century, "Freight and passenger traffic would thus both have to be served . . . and railroads, turnpikes and waterways carried significant amounts of each. It was common to lump both together by viewing these transportation facilities as 'means of communication'."[18] Thus the opening up of the west, for example, required both people and commodities to move back and forth. Settlers could be herded into freight trains and "shipped" west like other "commodities," including settlers' effects. In fact, many were.

The foregoing suggest several reasons why the distinction is more significant than it might have seemed in the past. One is that the safety issue now looms larger. The difference between loss and damage claims for commodities is of far less concern than death and injury to passengers. In a nation spending vast amounts to improve the health and safety of its citizens, death and injury from transportation of people has taken on new importance. This of course includes private automobile travel as well. But concern for such issues has risen from a fatalistic "acts-of-God" notion to one that society has created by its own technological advances in transportation and elsewhere. It is now incumbent to direct resources to alleviate such hazards to the extent possible. Highway and airway safety concerns have taken on new dimensions as new technologies both create more potentially dangerous situations and provide increasing opportunities for remedial or preventive actions. These include the so-called "smart" cars and highways, improved aircraft guidance and control systems and soon, stricter safety enforcement measures and the concomitant rise of damage claims for safety violations and accidents. In short, the provision of passenger service by any firm is attendant with concerns for the safety of the passengers that is greater than those in the case of freight.

In addition, comfort has now become far more significant if only because the private car provides a convenient reference point for both comfort and convenience that is hard for a commercial carrier to match. A successful commercial operation requires a degree of concern and ability to address these matters which are highly personal, that no freight agent ever had to contend with.

This suggests several things. Since the cost and demand elements are so different in the markets for freight and passenger intercity transportation and since societal rules of the game, so to speak, have shifted substantially in the direction of human safety and comfort, and other quality dimensions, the capabilities of those providing passenger services are significantly different from those who transport goods. What is an adequate railroad bed for freight traffic will no longer suffice for the smooth ride demanded by passengers accustomed to smooth highways or airways. Indeed new transport technologies, such as maglev need their own distinct right of way. It seems clear that rail passenger traffic will require separate, differentially maintained and perhaps unique rights of way if railways are to carry people. More generally, the present trend toward separate management of goods and people movement will probably continue. Air, truck, rail and water cargo carriers will increasingly involve companies totally divorced from significant passenger movements and vice versa. Amtrak and the other proposals for high-speed rail passenger intercity travel involve self-owned rights of way and separate corporations or ownership. No longer can one expect a single railroad to move relatively large numbers of people in a predominantly freight business.
